For historical reasons, the Mexican-origin population is residentially concentrated in the five Southwestern states, especially California and Texas, and Illinois (Bean and Tienda, 1987). Within these locations, Mexican migrants tend to reside in the inner cities of the largest metropolitan areas. Moreover, Los Angeles, Chicago, San Antonio and Houston contain sizable established Mexican-American communities. The residential concentration of Mexican migrants bears on impact assessments for several reasons. First, existing studies are clear that the strongest impacts occur in areas of greatest concentration, and often accrue to earlier immigrants, who are good labor market substitutes for their recently arrived compatriots. Second, geographic concentration of population makes possible scale effects, although many of these are not easily measured and may be arbitraged through other mechanisms, including secondary migration of native populations. Third, political impacts and cultural imprints on the host society are contingent on geographic concentration, to some extent, as we elaborate below.

Undocumented Migration

Not only is Mexico the single most important source of legal immigrants, it is also the primary source of unauthorized migrants. Representative data on undocumented migrants are necessarily sketchy, but studies of the legalized population indicate that 70 percent of undocumented migrants granted amnesty

under the provisions of the immigration Reform and Control Act (IRCA) of 1986 were of Mexican origin (see Tienda, et al., 1991; Borjas and Tienda, 1993; Singer, 1994). Although IRCA included provisions for tighter border enforcement, the undocumented stream has continued to increase in recent years. Between 1989 and 1994, the U.S. Border Patrol located 6.4 million entries from Mexico who were deemed deportable. Tienda and Singer (1995: Table 1) reported that roughly 90 percent of Mexicans who adjusted their legal status under IRCA resided in three states: California (61 percent); Texas (17 percent) and Illinois (11 percent). This implies that these three states bear the brunt of costs and benefits associated with undocumented migration.

Legal status of migrants is important for understanding the impacts of Mexican migration because public attitudes and behavior toward migrants from Mexico are often driven by images, accurate or not, of undocumented migrants. Employers who fear sanctions for hiring migrants who entered the United States unlawfully may deliberately avoid hiring all workers who look and sound like foreigners. Such behavior could directly affect the employment and wage opportunities of earlier arrivals who entered legally, as well as some native residents who speak English with an accent or "look Mexican." Although these effects are difficult to quantify, there is little disagreement that the presence of a large share of undocumented migrants among the Mexican migrant population shapes the policy and social climate surrounding Mexican migration to the United States. Moreover, beliefs that undocumented migrants are heavy users of tax-funded social programs has triggered legislative initiatives to restrict access to social programs by all migrants, including legal, non-citizen immigrants and undocumented migrants. We discuss this issue in some detail because Mexican migrants—both documented and undocumented—are at the center of the debate by virtue of their residential concentration in California, the state responsible for most initiatives to curtail access of migrants to social programs.

Labor Market Skills

Among recent and prior migrants, Mexican-born migrants feature the lowest levels of formal schooling and English proficiency. Both characteristics are important determinants of labor market success and the likelihood that immigrants will not become public charges. Tables 1A through 1F provide summary education and English proficiency statistics for Mexican migrants, compared to other foreign born, U.S.-born Mexicans, whites, and blacks separately for men and women residing in California, Texas and Illinois in 1990.[8] The lowest level of education corresponds to the Mexican foreign-born population in all three states (as well as the national population) and for both sexes.

[a] Conditional on being in the labor force
Source: 1990 PUMS 5% file

Focusing on the population in the prime working ages (25-54), foreign-born Mexican men and women averaged 7.5 to 8.2 years of education, compared to between 11 and 12 years for the U.S.-born Mexican men and women. Residents of Illinois average slightly higher education levels owing to the larger shares who received high school diplomas (30 versus approximately 25 percent for California and Texas residents). Other foreign-born men and women in their prime working ages averaged 12 to 13 years of education, depending on their state of residence, as did native white and black men and women.

Older men and women born in Mexico (ages 55 and over) completed even fewer years of graded schooling than their younger counterparts, usually six or fewer years. Mexican-born men and women who resided in the United States in 1990 were less proficient in English than their age counterparts born in other countries. Undocumented migrants from Mexico have especially low levels of formal schooling. Tienda and Singer (1995: Table 10) reported that Mexicans legalized under the IRCA amnesty program averaged 6.9 years of formal schooling compared to 9.4 years for those from other Latin American countries. Undocumented migrants from other regions of the world averaged 13.7 years of formal schooling.

The skill composition of Mexican migrants has important and profound implications for addressing questions about labor market impacts, and in particular, whether Mexicans compete mainly with other low wage workers (e.g., native-born teens, women, blacks, unskilled Mexican Americans and migrants who arrived earlier), or whether Mexican migrants fill labor market niches that domestic and other foreign-born workers do not want. In light of recent trends in U.S. wage inequality between skilled and unskilled labor groups, the question of whether large numbers of unskilled Mexican migrants can be absorbed in the labor market remains a central source of controversy about the U.S. impact of Mexican migrants.

Labor Market Profile

Based on their educational characteristics, Mexican migrants would appear to be at a disadvantage in competing for U.S. jobs and wages relative to other population groups compared in Tables 1A-1F. However, the evidence is mixed. Mexican-born men have consistently higher age-specific labor force participation rates than native blacks in all states considered in Tables 1A-1F, but this is not so for women, among whom native blacks have the participation advantage. Moreover, at younger ages, Mexican migrants have a substantial labor force participation advantage over their U.S.-born counterparts. Tienda and Singer (1995: Table 1) reported high labor force participation rates among newly legalized immigrants, around 95 percent for men. Mexican migrants experience higher unemployment rates than Mexican Americans, other immigrants, and native whites, but they do not always have higher

unemployment than native blacks. The disparity in labor force participation and unemployment rates between Mexican migrants and blacks is especially pronounced in Illinois, where inner city joblessness has risen dramatically since 1970 (Wilson, 1987; 1996). These two comparisons—labor force participation rates and unemployment rates—are highly relevant for a study of impacts not only because Mexican migrants are disadvantaged relative to blacks and Mexican Americans in terms of the language and educational credentials they bring to the labor market, but also because they bear on questions about job competition and displacement.

For historical reasons detailed by Verduzco and Unger (this volume), Mexican migrants are highly concentrated in agriculture and other extractive industries. Table 2A shows that among men ages 16 and over who resided in California in 1990, 17 percent of Mexican migrant men were employed in agricultural jobs compared to under 3 percent of other foreign-born men, and under 5 percent of U.S.-born Mexican origin men. Even among women, those born in Mexico were disproportionately concentrated in agriculture, where they accounted for 8 percent of industry employment compared to under 2 percent for U.S. Mexican-origin women (Table 2B).[9] Less than 1 percent of other foreign-born women who resided in California and were employed in 1990 worked in agriculture. Mexican- born men also find jobs in construction, nondurable manufacturing and retail trade, each sector absorbing over 12 percent of the employed. For Mexican migrant women, durable and nondurable manufacturing, retail trade and business repair services are important employment sectors.

In Texas, another state where Mexican workers historically have been concentrated in agriculture, about 11 percent of all Mexican migrants were so employed in 1990, compared to less than 3 percent of other migrants and about 5 percent of Mexican Americans. However, in Texas nearly one in four Mexican migrant men were employed in construction, the modal employment sector for them but no other group. In Texas foreign-born men from places other than Mexico were concentrated in retail trade (their modal employment sector), business and repair services, and nondurable manufacturing. Among employed migrant women who resided in Texas in 1990, nearly one-in four worked in retail trade and there were no differences between those born in Mexico and elsewhere in this respect. However, Mexican-born women living in Texas were more likely to work in manufacturing goods compared to other migrant women, 15 versus 6 percent, respectively.

Because Illinois does not have as large an agricultural sector as either California or Texas, the shares of Mexican migrants who work in this sector are somewhat lower than those for California or Texas, but still much higher than the shares of other male migrants and Mexican Americans so employed. Among the foreign born residing in Illinois in 1990, nondurable manufacturing was the modal employment sector, but relatively larger shares of Mexican-born men and women compared to

migrants born elsewhere were so employed. In striking contrast to Mexican migrants residing in Illinois, nearly one-third of the foreign born from other countries were employed in professional business service industries. In this respect, Illinois' non-Mexican migrants were quite similar to native whites and blacks, and quite unlike Mexican migrants. These differences are especially evident for the female labor force in Illinois.

The index of dissimilarity reported in the lower row of each panel of Tables 2A and 2B provide a useful way to summarize the differences in the industrial distribution of employed Mexican migrants relative to native-born white men and women, respectively. This index indicates the share of the labor force that would have to change industries to reach parity with the native white labor force. These entries reveal that the industry distribution of employed Mexican migrants is more dissimilar from that of native whites than are any industrial distributions of the other groups. Moreover, the differences in industrial distributions between Mexican migrants and native whites are larger for women than for men, although the magnitude of the differences varies across states. These differences have implications for the nature of job competition between Mexican migrants and other demographic groups, but they are also related to human capital that migrants bring to the U.S. labor market and their earnings possibilities upon employment.

These differences are illustrated in Tables 3A through 3F, which tabulate for each of the three states the mean (1989) annual earnings of persons born in Mexico according to industry of employment and compares them with native whites, blacks, Mexican Americans and other foreign born. Although this table contains an enormous amount of information, several important generalizations are warranted. First, without exception, Mexican migrants received the lowest average annual earnings in every industry and each state, but it is unclear whether this is exclusively a result of their lower levels of education, limited proficiency in English, variation in annual hours worked, higher levels of employment instability in the course of a year, or wage discrimination. Second, annual earnings of Mexican migrant women are consistently below those of their male migrant counterparts employed in similar industry sectors. These differences can not be attributed to unequal educational attainment, as gender differences in formal schooling are relatively small among Mexican migrants. Third, Mexican migrants residing in Texas received lower annual earnings in each industry than their counterparts employed in similar industries in either California or Illinois. These differences are important for labor market impacts because they suggest that the Mexican-born population competes most directly with native-born persons for low-wage jobs, with Mexican-born women competing for the lowest wage jobs. These differences also are important for fiscal impact analyses inasmuch as they represent unequal levels of taxable income.

[b] Samples too small for reliable estimates

Source: 1990 PUMS 5% file

In sum, current rates of labor force participation and industry employment profiles are crucial for understanding the labor market impacts of Mexican migrants, although cross-sectional estimates do not reveal whether Mexican migrants are subject to greater levels of employment instability, or whether they draw disproportionately on the unemployment compensation system. Furthermore, labor market activity rates also influence the likelihood that Mexican migrants will be eligible for means-tested income transfers, which bears directly on questions of fiscal impacts, and indirectly on social consequences. Like educational attainment and rates of labor force participation, the employment profile of Mexican migrants has direct implications for an assessment of economic and social impacts because education and earnings positions situate Mexican migrants in the U.S. stratification system, and because their disproportionate concentration in low-wage employment raises the possibility that Mexican migrants compete with domestic low-wage workers, notably teenagers, minorities, and women. We address these and numerous additional issues concerning the impacts of Mexican migration below.

Impacts Assessment

Our assessment of impacts, which is based on a scrutiny of existing literature and several original analyses and tabulations, begins with an overview of demographic impacts, including those projected by the U.S. Bureau of the Census should current levels of immigration continue. We concentrate on economic impacts because most existing studies emphasize this dimension of the consequences of immigration, in particular, the labor market and fiscal impacts. However, the final section considers various social and political issues, including recent evidence on residential segregation, neighborhood transformation, economic mobility, crime, and attitudes toward Mexican migrants.

Demographic Impacts

Demographic impacts of migration from Mexico derive from changes in population size and annual growth rates and changes in population composition, especially age structure and race/ethnic make-up. The demographic impact of Mexican migration also derives crucially from (1) the intensity of the flow over time; (2) the highly concentrated settlement patterns of recent and earlier arrivals; and (3) the reproductive behavior of foreign-born women. Fertility of foreign-born women determines the age structure of future generations, and thus the longer term impact of recent migration trends for future population growth. The settlement patterns of recent and prior arrivals determines the ethnic landscape of cities and states where Mexicans settle and form communities. And, the volume of migration influences

both the size and growth of the Mexican-origin population both directly through numbers added and indirectly through differential fertility and mortality. All these dimensions of demographic change are crucial for understanding the social and cultural impacts of Mexican migration, as well as the integration experiences of the migrants themselves, which in turn transmit different impacts.

In this section, we review recent population trends and projections with the goal of identifying how migration, and that from Mexico in particular, has contributed to various aspects of demographic structure. First, we describe changes in the size and composition of the Mexican-origin population during the past quarter century, from 1970 to 1996. We pay special attention to changes since 1980 because the Spanish-origin identifier allowed for more consistent and comprehensive measurement of the Mexican-origin population (Bean and Tienda, 1987; Tienda and Ortiz, 1986), and because the intensification of the migrant stream during this period has direct implications for current and future impact assessment. Second, we summarize population projections prepared by the U.S. Bureau of the Census, the National Academy of Sciences, and the Urban Institute, and draw inferences about the future Mexican-origin population.

Population Growth

In 1990 the foreign-born numbered just under 20 million, comprising about 8 percent of the U.S. population. By 1996 the foreign-born population approached 25 million, still well below the historic high of nearly 15 percent registered at the turn of the century. Mexicans accounted for approximately 22 percent of the 1990 foreign-born population and about 27 percent of the estimated 24.5 million foreign born residing in the United States in 1996 (Hansen and Faber, 1997). That about 27 percent of the 1996 foreign-born population arrived after 1990, and an additional 35 percent were admitted during the 1980s reveals how the intensity of migration has been increasing over all, and for Mexicans in particular (see Table 4).

As a component of demographic change, international migration has commanded relatively less attention than either mortality or fertility partly because the U.S. population has been growing slowly during the past two decades, and partly because net migration has not been a major component of population change in the past.[10] However, immigration can produce potentially large impacts on population size, rate of growth, and composition and is likely to do so in the future if current trends continue. Already recent trends have left an indelible demographic imprint. In 1970, just under 5 percent of the U.S. population was foreign-born. By 1996, a quarter century later, this number nearly doubled. During this period international migration accounted for between 25 to 33 percent of net annual population increase (U.S. Bureau of the Census, 1996; Fix and Passel, 1994). In

the future, current levels of immigration can become an even larger component of population growth if fertility remains below replacement (as it has been for nearly two decades) and longevity remains constant or increases. Under these conditions, the impacts of immigration as a component of net growth will increase.

Although slightly more than 1.1 million migrants arrived each year during the past decade or so, the net annual increase of the foreign-born population is about 700,000 each year (Fix and Passel, 1994:23). This is because mortality and emigration (mostly involving recent entrants) reduce the foreign-born population by an estimated 200,000 annually. Mexico has accounted for a highly variable share of legal U.S. immigrants admitted during the past three decades, which in turn result in highly variable contributions to population increase. During the 1960s and 1970s, approximately 14 percent of all legal immigrants admitted were from Mexico. This share rose to 23 percent during the 1980s owing to the impact of the legalization program (INS, 1997: Table 2). The contribution of IRCA legalizations to total Mexican immigration was most pronounced in Fiscal Years 1989 through 1991, when the Mexican share of legal immigration (including adjustments to legal status) rose appreciably from 37 percent in 1989 to 44 percent in 1990; then to 52 percent in 1991 and 22 percent in 1992. Thereafter, the Mexican share of total immigrants admitted stabilized at its pre-IRCA level of 12 percent or so (INS, 1997: Table 2). With total immigration accounting for between one-third to one-quarter of annual population growth, the direct contribution of legal immigration from Mexico to U.S. population growth is small during the non-IRCA years (about 3 to 4 percent) and modest during the IRCA years (about 10 to 13 percent). Thus, legal immigration from Mexico accounted for between 3 to 13 percent of total population growth.[11]

Although Mexican migration has been a relatively small component of net aggregate population growth, its impact on the size of the Mexican-origin population, and the population of selected states where most recent arrivals settle is far more substantial. Bean and Tienda (1987:66) concluded that migration was responsible for less than half (and substantially less than half for legal immigrants) of the growth of the Mexican-origin population between 1970 and 1980. At that time, only one in four persons of Mexican origin were foreign born. By 1990, and in the wake of both the large volume of IRCA legalizations and continued immigration from Mexico, nearly one in three persons of Mexican origin were foreign born (U.S. Bureau of the Census, 1993: Table 1). INS (1997: Table 2) reports that nearly 1.6 million Mexicans were admitted as legal U.S. residents between 1981 and 1990; an additional 1.5 million were admitted in Fiscal Years 1991-1995.

Secondary (or indirect) demographic impacts attributable to Mexican migration derive from the differential fertility of native- and foreign-born women of Mexican origin. In 1990, the average number of children ever born to Mexican-origin women

aged 25 to 34 were 1.7 and 2.1 for the native and foreign born, respectively. Among women aged 35 to 44, the nativity differentials in children ever born were greater still—2.5 for U.S.-born women compared to 3.3 for Mexican-born women. These differences in child bearing influence future population growth through changes in the age structure and its associated future momentum. Moreover, the current and future demographic impacts, particularly those associated with the school-aged population and the future force entrants, will be most pronounced in localities where Mexican migrants are residentially concentrated.

Relative to the native-born Mexican-origin population, legal immigrants from Mexico are older. The median age of the native-born Mexican-origin population has risen slowly, from 18.4 in 1960 to 20.5 in 1980 (Bean and Tienda, 1987), to 23.7 in 1990 (U.S. Bureau of the Census, 1993a). As a result of the changing age structure of recent migrants and the aging of earlier migrants, the foreign-born Mexican-origin population became more youthful between 1960 and 1980, with the median age declining from 42 in 1960 to 29 in 1980 (Bean and Tienda, 1987: 67; U.S. Bureau of the Census, 1993: CP-3-3: Table 1). High fertility of all Mexican-origin women relative to non-Hispanic white women also contributes to a youthful age structure, which is reflected in the median age of 17-18 between 1970 and 1990 (Bean and Tienda, 1987; U.S. Bureau of the Census, 1993). These changes in age composition are significant for assessing the economic consequences of Mexican migration because they alter the relative shares of school-aged and working-age population as well as the elderly.

That females predominate in recent cohorts (with the exception of those involving the IRCA legalizations) also has implications for the future demographic impacts of Mexican migration. For example, the median age of female Mexican immigrants legally admitted in 1995 was 25—the peak of women's reproductive years. In this connection, two aspects of women's reproductive behavior are noteworthy. First, Mexican migrants bear more children than migrants from other regions of the world of comparable social and economic characteristics (Bachu, 1991).[12] Second, the larger completed family sizes of Mexican migrant women result from childbearing after migrating to the United States rather than having initially larger families when first entering the United States. This is contrary to predictions based on assimilation theory and differs from the fertility behavior of other immigrant women. More generally, this implies that the secondary effects of Mexican migration are likely to be larger than those of other migrant women.

Residential Distribution

A second important facet of demographic impacts of Mexican migration stems from the U.S. settlement patterns of recent migrants. The foreign-born population,

but especially recent arrivals, is residentially concentrated in six states—California, Florida, Illinois, New York, New Jersey and Texas. Two of every three immigrants legally admitted in 1995 chose these states as their destination, which have been the leading states of intended residence since 1971. Because California has been the first choice of residence every year since 1976, it currently houses the largest foreign-born population both in terms of numbers (an estimated 8 million as of 1996) and share of the state's population (one-fourth of the total population is foreign born). Other states with at least one million foreign-born residents include Florida, Texas, New Jersey and Illinois (Hansen and Faber, 1997:2).

Mexican migrants were residentially concentrated in three of these states—California, Illinois and Texas. In 1970, just over one-fourth of the foreign-born population resided in these three states compared to 86 percent of the Mexican-born population: 54 percent in California; 6.6 percent in Illinois; and 25.5 percent in Texas. By 1980 the share of the total foreign-born population residing in these three states rose appreciably from 28 to 37 percent, most in California, and the share of the Mexican foreign-born population residing in these states increased slightly to 88 percent (58 percent in California; 7.6 percent in Illinois; and 22.6 percent in Texas). During the 1970s, the Mexican share of the foreign-born population rose from 7.9 to 15.6 percent.

The 1980s and 1990s witnessed an intensification of these two demographic trends, namely, a rising share of Mexicans among the foreign-born population (from 15.6 to 22 percent of the resident foreign-born population) and the continued residential concentration of all migrants in California, Illinois and Texas (up from 37 percent in 1980 to 45 percent in 1990). In 1990, about 85 percent of all Mexican migrants resided in these three states compared to just under half (45.2 percent) of all migrants.[13] The increased residential concentration in these three states coupled with the persisting residential concentration of all Mexican migrants has two important implications for understanding the social impacts of Mexican migration. One is that some of the demographic (as well as economic and social) impacts deriving from other migrants (especially those from Central and South America) may be attributed to Mexican migrants. Another is that the social and economic impacts directly attributable to Mexican migration will be most pronounced in these three states for the foreseeable future. This is so even if migration were stopped completely because of the secondary effects deriving from the changed age and race composition as well as differential fertility and mortality associated with the youthful populations. Accordingly, we spotlight these three states in our assessment of economic and social impacts below.

Population Projections

According to the Census Bureau's most recent projections, the U.S. population is expected to increase by 50 percent between 1995 and 2050, from 263 million to 394 million (U.S. Bureau of the Census, 1997). The U.S. population is expected to grow slowly even in the absence of immigration. However, zero immigration is an implausible scenario at present. Below replacement fertility rates coupled with continued, albeit modest, increments in longevity, means that immigration will be a larger component of future population growth (U.S. Bureau of the Census, 1996:23). Census Bureau projections do not separately identify immigrants by country of origin, but their projections are helpful in drawing inferences about Mexican migration insofar as they identify plausible changes in the size of the Hispanic-origin population. We know that Mexicans comprise slightly over 60 percent of all Hispanics, and this share has remained relatively stable at least since the early 1970s (Bean and Tienda, 1987: Table 2.2). Recent trends also indicate that migration was responsible for about half the growth of the Mexican-origin population, and that foreign-born share has risen gradually over successive censuses (Bean and Tienda, 1987; U.S. Bureau of the Census, 1993).

The recent National Academy of Sciences (1997: chapter 3, p.26) report on the consequences of immigration considered how the U.S. population would have evolved in the absence of immigration since 1950. The panel concluded that the U.S. population would have been 14 percent smaller than its 1995 size and that it would have been considerably older. Projecting forward current levels of immigration for 50 to 55 years would increase population by 80 million above what would occur in the absence of any immigration.[14] This net increase reflects the direct result of 45 million new immigrants plus the dual indirect effects of higher immigrant fertility and the lower overall mortality of a more youthful first and second-generation migrant population. Under this scenario, immigration will represent an increasing share of population growth over time. As the single largest national origin group in recent years, Mexicans would account for approximately 10-12 percent of the increase at the base year, compounded by their higher fertility and young age structure.

Two important composition changes follow from the current level and country of origin composition of migrant streams. First, current migration levels will increase future enrollments in primary, secondary and college enrollments relative to lower migration levels. Second, owing to the predominance of Latin American and Asian migrants in recent streams, the race and ethnic composition of the U.S. population will change dramatically, favoring the increase of Asians and Hispanics. According to the U.S. Census Bureau's (1996:15) projections, the growth of the Hispanic population will probably be a major element of total demographic growth, contributing 37 percent of growth from 1995 to 2000; 44 percent from 2000 to

2020; and 62 percent thereafter. However, this growth may be fueled more by the indirect effects of migration on fertility than by migration directly. As a result of this growth, the absolute and relative sizes of Asians and Hispanics will more than double (3 to 8 percent for Asians and 10 to 26 percent for Hispanics). Alternatively, if there were no net immigration after 1994, the race and ethnic composition of the U.S. population would be quite different than projected by the middle series (which approximates the current admission regime).

Within the middle immigration scenario, the growth of the Mexican-origin population is likely to increase far more than the other Hispanic-origin groups for several reasons: First, Mexicans comprise the largest source country of current migration. Among the top 20 countries of birth admitted in Fiscal Year 1995, only the Dominican Republic and Cuba ranked in the top 10, but even the fourth-ranked Dominican Republic sent less than half as many migrants as Mexico (INS, 1997). Second, fertility of both native and foreign-born Mexican-origin women will likely contribute to relatively faster population growth (U.S. Bureau of the Census, 1996:15). Third, the 1995 Mexican-origin population is larger and relatively younger than other Hispanic-origin groups, providing a bigger base from which to compound future indirect effects (fertility of migrants and lower mortality of the younger population). Finally, Mexicans have been the largest source of undocumented migration in recent years, and this flow is unlikely to end even if the size of the future undocumented population shrinks (owing to tighter border controls).

Of course, all projections become less reliable the further in time one extrapolates, but the conclusion that immigration generally and Mexican migration in particular will be a major component of future population growth is all but assured. Less clear are the relative components of growth due to fertility, as well as legal and illegal migration.

Conclusions about Demographic Impacts

Several conclusions follow from this discussion. First, Mexican migration has become *spatially* as well as *temporally* concentrated, thereby confining the first and second order impacts to three states: California, Texas and Illinois. The residential concentration of Mexican migration coupled with rapid growth has changed the ethnic landscape of major cities in these states.

Second, although immigration has not been a major component of population growth in the past, its influence on demographic change has been increasing. And, as immigration becomes a larger component of population growth and change, so too will Mexican migration exert more pronounced demographic, and thereby economic and social impacts. If current migration trends continue, the demographic impact on the Mexican-origin population will increase over time, as it will be

compounded by higher fertility and mortality of Mexican-origin women, and the lower mortality at younger ages. That these trends are currently underway is evident in that the Mexican share of the foreign-born population has been rising (from 22 to 27 percent during the 1990s alone) and the foreign-born share of the Mexican-origin population has increased from one in four to one in three during the 1980s.

Third, because the share of ALL migrants who settle in California, Texas and Illinois has been increasing over time, it is difficult to disentangle the impacts due to Mexican migration from those due to other migrant groups who settle in areas where Mexicans are highly concentrated, particularly those from Central and South America.

Labor Market Channels of Influence

Theoretical Principles[15]

Before presenting empirical evidence about the labor market impacts of Mexican migration to the United States, we develop a simple model of international migration to describe theoretically some of the basic points of contention in the debate regarding the economic effects of immigration (Greenwood and McDowell, 1986; 1993). For simplicity, consider the United States as a country of immigration that produces a single, nonexported output by means of two inputs, capital and homogeneous labor. The left panel of Figure 1 depicts a situation in which the world supply of labor (e.g., Mexican labor) is perfectly elastic at wage rate W_e. The right panel shows a hypothetical model of the U.S. labor market. If labor were to seek its maximum earnings, if transportation and other costs associated with moving were negligible, and if institutional impediments to the free flow of international migration were nonexistent, cd = a'd' workers would migrate to the United States. Consequently, U.S. labor supply would increase from S_{us} to S''_{us} and its wage rate would fall to the world equilibrium level at W_e. If the United States were completely and effectively to close its borders, its wage rate would be W_{us}. In this simple model, because labor is homogeneous, foreign-born labor is a substitute for native-born labor.

Suppose instead that for political, economic, humanitarian, or other reasons, the United States imposed a binding quota of ab = a'b' workers, allowing an increase in labor supply from S_{us} to S'_{us}. This increase has two important consequences. First, the domestic wage rate falls to W'_{us} and total employment rises from **oe** to **ob**. However, domestic employment declines by **ae** workers from **oe** to **oa**. Thus, to some extent (i.e., **ae**) immigrants displace domestic workers. Second, when the wage rate falls from W_{us} to W'_{us}, labor earnings change from **0xze** to **0trb**, of which **0sta** accrues to indigenous workers and **asrb** to immigrants. The earnings of indigenous workers have fallen from **0xze** to **0tsa**. On the other hand, returns

to nonlabor factors of production have risen from **xyz** to **tyr**. The clear implication is that some groups in the United States benefit from immigration, while others bear the costs.

An existing wage differential of (W'_{us} - W_e), to the extent that it reflects its real-world counterpart, is substantial. For example, Mexico is the single major supplier of U.S. migrants, and wages available in the United States are between 5 and 13 times higher than those available in Mexican agriculture.[16] Given such a wage differential, the continued build-up of demand for entry into the U.S. labor market from abroad would be expected. Of course, information concerning the availability of the wage differential is not freely available to all potential migrants, as the model implies, and transportation and psychic costs associated with international migration may be appreciable. Nevertheless, the potential supply is still substantial, even if relatively nearby sources, like Mexico, the West Indies, and Central America, are the primary origin areas.[17]

The magnitudes of the wage and employment changes consequent upon immigration are dependent upon the elasticities of labor demand and domestic labor supply, the magnitude of the quota, and other assumptions implicitly embedded in Figure 1. In general, the more inelastic are the demand and supply relationships, the greater will be the reduction of domestic wages due to a given amount of immigration. Moreover, the displacement effect will be greater the more elastic is domestic labor supply and the less elastic is labor demand.

One of the most troublesome assumptions in Figure 1 is that labor is homogeneous. This assumption rules out the possibility of uneven impacts among various labor force groups. The introduction of two classes of labor (i.e., skilled and unskilled) permits greater focus on the low-wage labor market, which has commanded considerable research attention by analysts of rising wage inequality.[18] If the composition of Mexican migrants is oriented toward less-skilled workers, the most directly relevant demand and supply elasticities are those in the low-wage labor market. Relaxing the assumption of homogenous labor is further appealing because it raises the salience of skill transferability and questions about the economic adaptability of immigrants and their offspring to the receiving society. Moreover, with two classes of labor and with capital, immigrants and natives may be either complements or substitutes in production. If immigrants and natives are complements, the demand curve for complementary native workers would shift out, such as from D_{us} to D'_{us} in Figure 1. If they were substitutes in production, native demand for substitutable native workers would shift in the opposite direction.

As noted above, the transfer of resources inherent in international migration also results in a redistribution of income between origin and destination countries. In Figure 1 the area **ezrb** represents a net addition to national output in the country of immigration. As long as the migration is motivated by a positive wage

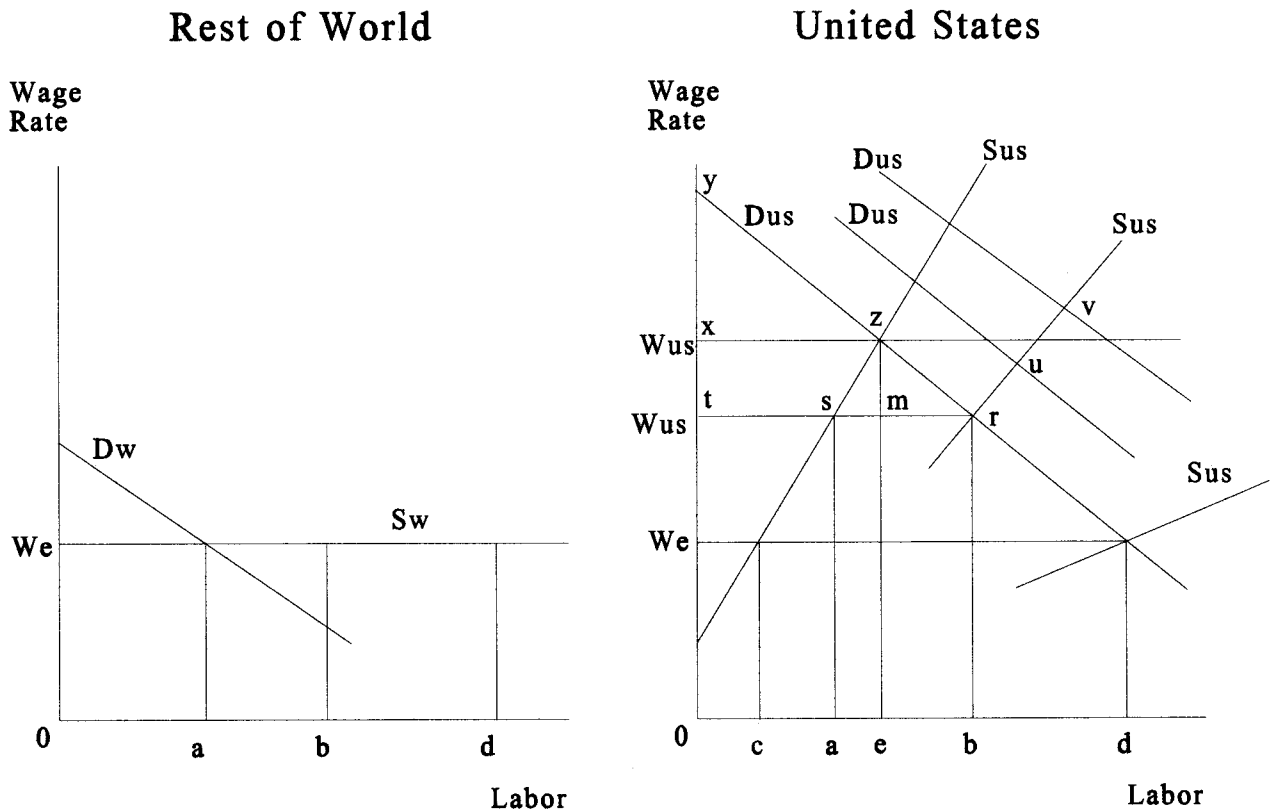

Figure 1. Labor and Wage Rate: U.S. and the Rest of the World

differential, the loss of output in the country of emigration would presumably be less than this magnitude, and global output would rise.[19] The effects on the country of origin would be greater or less, depending on the employment status (unemployed, underemployed, not in the labor force) of migrants. The assumption implicit in the left panel of Figure 1 is that the migrants do not affect employment in the source countries. Relaxing this assumption opens up the possibility of the brain-drain phenomenon.

Another problem with the simple, static, partial equilibrium model developed here is that it ignores many important features of an expanding, dynamic economy. For instance, Bernard (1953:57) attacks the so-called lump of labor fallacy, suggesting that "job opportunities in any society are not fixed at any particular level but expand with a rising population." Bernard argues that through their consumption, immigrants expand the market of the receiving society. They also stimulate increased investment expenditures, thereby further contributing to increased aggregate demand. Moreover, immigrants contribute importantly to technological progress and entrepreneurial activity (i.e., technological externalities). Simon (1981) shares the view that in the long run, immigrant contributions to technical progress positively affect per capita income. In terms of Figure 1, Bernard suggests that immigration shifts both the labor supply and labor demand schedules outward, but he does not explain why the demand shift should dominate the supply shift (e.g., point v). If the supply shift dominated the demand shift (e.g., point u), wages would fall and indigenous workers would be displaced, though not to the extent that would have happened had no offsetting demand shift occurred (e.g., point r).

Bernard's position (i.e., point v in Figure 1) is certainly plausible, but does not appear to have an important place in the present debate, at least in so far as the aggregate U.S. economy is concerned. Substantial quantitative evidence suggests that this condition may have prevailed in the U.S. up to 1900 and perhaps even to 1920, during which time aggregate scale economies probably existed. The consensus appears to be that such conditions have not existed during the last half century, and therefore equilibria such as v are unlikely to hold at the present time.[20] Not only might the immigrants themselves contribute to an outward shift of D_{us} (Bernard, 1953), but also aggregate labor demand is likely to be growing due to other forces such as growth of aggregate income. Depending upon how fast domestic labor supply is growing relative to demand, immigrant "absorptive capacity" could be greater or less than might be implied by a static model.

Empirical Evidence

Empirical studies about labor market impacts of immigration have been concerned with two related questions: (1) Do immigrant workers depress the wage

rates of domestic workers and, if so, which domestic workers? (2) Do immigrant workers displace certain domestic workers from their jobs, or through various channels do immigrant workers increase employment opportunities over and above their own contributions to employment. The answers to these questions are related in part to whether immigrants and natives are complements or substitutes in production. Although much effort has been devoted to addressing these questions, the empirical evidence is inconclusive. Answers depend on the level of aggregation of the analysis; assumptions about whether (and how) the labor market is segmented; the temporal frame of reference; the methodology used; and the migrant characteristics, notably education level and years since migration. That Mexican immigrants have low levels of education and are heavily concentrated in the Southwest implies that labor market impacts most likely will be concentrated within the low-skill segments of these particular markets. Although the initial impacts of immigrants differ from the ultimate impacts, few studies have examined this aspect of immigration.[21] Especially understudied are the intergenerational consequences of immigration (for an exception, see Borjas, 1992).

Aggregate and Group-Specific Impacts

Several empirical studies employ a production-theory approach to determine the substitutability between capital and various groups of native- and foreign-born workers. In spite of nontrivial methodological differences and in time period analyzed, several major studies concluded that immigrants have had very small (negative) impacts on the earnings and employment opportunities of the native-born population (Grossman, 1982; Borjas, 1986a; Greenwood, Hunt and Kohli, 1996, 1997). These studies assume an instantaneous adjustment to exogenous changes in labor supply, and essentially ignore the important question about how quickly local economies adjust to an exogenous change in labor supply. Even though the resulting change in wages may be small, adjustment costs may be large.

Prior Evidence of Labor Market Impacts. The wage and employment impacts of immigrants on native workers may differ according to race and national origin, but the findings of prior studies are highly variable. The empirical evidence generally indicates that immigrant groups tend to be substitutes for some domestic labor market groups and complements for other domestic workers (Borjas, 1987a). Specifically, Hispanic immigrants appear to be substitutes for white domestic male workers, but complements with native Hispanic workers. Mexican immigrants have a small negative impact on the earnings of both white and black native-born men. However, all immigrants have a sizable negative impact on their own wage levels (see Borjas, 1986a, and 1986b).

Although Borjas finds limited evidence that immigrants are substitutes for the black native-born population, one study conducted within a human capital framework claims that recent immigrants from countries other than Mexico, Cuba, and the West Indies are substitutes for black males (see Stewart and Hyclak, 1986). Yet another study conducted within a human capital framework (King, et al., 1986) uncovers little evidence of substitution between migrants and second or third-generation Hispanics. However, among a subsample of laborers, negative effects of migrants on native workers emerge, but these too are relatively small (-0.1). In sum, *the preponderance of aggregate evidence about the complementarity and substitution relationships between native and foreign-born workers indicates that immigration decreases employment and wages of low-skill domestic workers by very little. These findings, based on 1970 and 1980 data, imply a highly inelastic supply of domestic low-skilled labor and a relatively elastic demand for such labor*.

Regarding the hypothesized negative impact of immigrants on various skill groups, Briggs has argued for over two decades (1975a; 1975b; 1995) that the low-skill segment of the U.S. work force, and the minority work force in particular, have borne the brunt of the labor market competition from immigrants to the United States. That young workers, and especially minority teenagers, are disproportionately represented among the least skilled and experienced domestic workers suggests that the negative effects of migrants will be greatest among minority teenagers. Contrary to this proposition, Borjas (1984b) estimates positive elasticities of complementarity between immigrants and young (i.e., 24 years of age or younger) native-born black men. This impact is not uniform across immigrant groups, however. For example, Borjas (1986b) finds that Hispanic immigrants exerted an insignificant and sometime negative impact on wages and earnings of young black men, whereas the impacts of non-Hispanic immigrants are consistently positive.

Other studies (e.g., Matta and Popp, 1988; Kimenyi, 1989) claim that the complementarity and substitutability of immigrant and domestic labor have changed over time, such that highly skilled immigrants from Europe were complements in production to black youth, whereas more recent, less-skilled migrants from the Americas are substitutes. That no study has adequately separated the effects of legal and undocumented migration weakens inferences about the dynamics of competition in low-wage labor markets, however. This is an especially important consideration for drawing inferences about the labor market impacts of Mexican migration. DeFreitas' (1988) view of immigration as a sequential process in which some newcomers integrate into ethnic job clusters and, over time, disperse from these enclaves to exert competitive pressures on low-skilled native workers seems to be a plausible explanation for some of the observed coexistence of complementary and substitution relationships.

Workers born in Mexico increase the supply of labor available in the United States. This increased labor supply clearly is not spread evenly across the United States, but rather is concentrated in proximity to the U.S.-Mexico border and in areas that offer those types of employment opportunities that are attractive to migrants from Mexico. Previous studies typically have shown that the wage and employment effects of increased immigration on native-born groups are not great. The largest impacts are on other foreign-born workers (like the migrants themselves). The results of earlier studies, however, have been based on 1970 and 1980 census data and on other data sources that are sufficiently old to throw into question their contemporary relevance. Moreover, the various studies that adopt a production function approach usually have not focused specifically on areas of high migrant concentration. The analysis reported below addresses both of these limitations of prior studies.

1990 Labor Market Impacts. In the discussion that follows, we assume that in each metropolitan area the technology can be represented by an aggregate production function that expresses output as a function of various labor inputs and capital. Using the Symmetric Normalized quadratic functional form introduced by Diewert and Wales (1987), we estimate a nine-input production function. The methodology for this analysis is detailed in Research Volume 3, pages 1078 to 1116. In addition to capital, the labor inputs in the Mexican Model are (1) native, low-skill Mexican males; (2) native, low-skill Mexican females; (3) native, low-skill non-Mexican males; (4) native, low-skill non-Mexican females; (5) native, high-skill; (6) foreign-born, low-skill Mexican; (7) foreign-born, low-skill non-Mexican; and (8) foreign-born high-skill.[22] Workers from Mexico tend to be low-skilled, and hence they compete most directly with low-skilled native- and foreign-born workers. The methodology used to estimate the models reported below allows for eight skill classes of labor, along with capital. Thus, six classes of low-skill labor are distinguished. Within the low-skill native group Mexican ancestry natives are distinguished from other natives, and each group is separated by sex. This separation by sex allows a focus on low-skill females, who have been ignored in most prior analyses. The foreign born are distinguished as Mexican and non-Mexican because we wish to simulate on low-skill, foreign-born, Mexican labor (i.e., increase employment of this group by a given amount and observe how this and other groups ultimately are affected through the workings of the model) and because we also wish to identify the labor-market impacts on this group.

Data for the estimation are drawn from the 1990 U.S. census. Metropolitan areas form the basic region that is the focus of the cross-sectional analysis. For the econometric model that provides considerable detail on native-born persons of Mexican ancestry as noted above, 122 metropolitan areas are used in the analysis.

This is the maximum number of usable areas. California and Texas each contain 23 of these areas. The various areas included in the analysis are reported in Appendix A.

Estimation of the production function relationships indicates that capital is a complement for all categories of labor except foreign-born high-skill labor. Overall, however, far more substitution than complementarity is apparent in the estimated relationships, and this is somewhat surprising. Most labor categories compete with each other. The strongest complementarity links are between native, low-skill men and low-skill foreign born, as well as between native, low-skill, non-Mexican women and high-skill foreign born. Based on the production function estimates alone, an increase in the number of low-skill Mexican migrants would tend to benefit capital and low-skill native males and hurt all other categories of labor. Except for low-skill Mexican migrants themselves, the estimated effects are very small.

In addition to the production structure channel of influence, the full model contains a labor force participation channel and an aggregate demand channel of influence. Table 6 reports results for a simulation of the full model. The basic simulation entails a 20-percent increase in the number of foreign born, low-skill Mexican workers. For all 122 areas, the average real wage of this labor group falls by 3.0 percent. Due to this lower wage rate, workers in this category withdraw from the labor force, so that ultimately employment of this group increases by 19.39 percent and not by 20 percent which reflects a displacement effect of about 0.6 percent (20.0 percent - 19.4 percent).[23] The wage rates of other labor categories are almost unchanged. For example, native, low-skill females of Mexican ancestry suffer a wage loss of only about 0.3 percent and their employment falls by about 0.2 percent. Thus, for the average U.S. region, even relatively large increases in Mexican-born labor do not appear to have large impacts on native workers.

Metropolitan areas in California and Texas have relatively heavy concentrations both of Mexican-born persons and of native-born persons of Mexican ancestry. As noted above, each of these states contains 23 metropolitan areas in the sample. The major impact of a 20-percent increase in foreign born, low-skill Mexican labor in California is on this group, whose wages fall by 6.9 percent (Table 6A) and whose employment declines by 1.3 percentage points (20 percent less 18.7 percent) (Table 6B). The largest wage impacts on other groups occur to foreign-born, low-skill, non-Mexicans and to foreign-born, high-skill persons, but in each case the effects amount only to about one percent. The labor displacement effect is never more than 0.5 percent for any group (Table 6B).

The results for Texas are similar to those for California, but for the most part are slightly more moderate. For example, when their employment is increased by 20 percent, foreign-born, low-skill Mexican workers in Texas suffer a 5.0 percent

wage decline (Table 6A) and about 1.1 percentage point job displacement (Table 6B). Comparable effects for Arizona, New Mexico, and Colorado (11 areas) are a 3.7 percent wage reduction and approximately 0.8 percent displacement. Areas of high concentration of foreign-born, low-skill Mexican workers clearly experience the largest impacts of a 20-percent increase in this labor category. For 13 areas for which this labor group constitutes 60 percent or more of the foreign-born population, the wage effect for a 20-percent increase in this group represents a decline of 11.4 percent. Employment of the group is reduced by 2.4 percentage points. Native, low-skill females of Mexican ancestry suffer a 1.3 percent wage decline and a 0.4 percent job displacement effect. Even these last effects are not large.

Three possibilities have been suggested for the repeated empirical finding that the effects of even relatively large increases in foreign-born labor do not appear to have great impacts on native workers. First, the foreign-born population is a relatively small fraction of the population and the labor force, and thus the effects may not be detectable. The results presented above suggest that even in areas with heavy concentrations of foreign-born, low-skill, Mexican labor, the wage and employment displacement effects of relatively large increases in this labor group are not great either for the native-born groups or for other foreign-born groups. The only noteworthy impact is on the own-wage rate because the members of the group are very good labor market substitutes for one another. A second possible explanation for the relatively small impacts of the foreign born on wages and employment is that offsetting increases occur in labor demand and supply relationships with the effect that the wage changes tend to cancel. A third explanation is that efficient U.S. markets result in the effects quickly arbitraging themselves across the nation, with the result that the effects are difficult to detect.

A closer examination of specific metropolitan areas in California and Texas and of other areas of high foreign-born, low-skilled Mexican concentration, indicate that the simulated wage and employment effects vary substantially. For example, among metropolitan areas in California, the own-wage reduction resulting from the 20-percent increase in foreign-born, low-skilled Mexican workers reaches as high as 15.2 percent in Visalia-Tulare and as low as 0.24 percent in Redding (Table 6A). Employment of foreign-born, low-skilled Mexicans is reduced by as much as 3.1 percent in Los Angeles and as little as 0.04 percent in Redding (Table 6B).

Similar variation in the magnitude of wage and employment effects is apparent among metropolitan areas in Texas. The wage reduction experienced by foreign-born, low-skilled Mexicans varies between 25.4 percent for McAllen-Edinburg-Mission and 0.5 percent for Beaumont (Table 6A). The group experiences employment reductions of between 6.1 percent in McAllen-Edinburg-Mission and 0.1 percent in Beaumont Table 6B). Also of note, wages of foreign-born, low-skilled Mexicans fall by 15.9 percent in Yuma, AZ, while employment falls by 3.4

percent. Greeley, CO, also has a high concentration of foreign-born, low-skilled Mexicans, although the own-wage reduction there is only 3.2 percent and the employment reduction is a mere 0.6 percent.

The range of the wage and employment effects on other groups resulting from a 20-percent increase in foreign-born, low-skilled Mexican workers is much smaller. Among metropolitan areas in California, the wages of native, low-skilled males (both Mexican and non-Mexican) increase, though this increase is relatively small and varies between 0.0 percent in Redding and 2.3 percent in Los Angeles (Table 6A). The wage effect is similar for metropolitan areas in Texas, reaching a high of 4.3 percent in McAllen-Edinburg-Mission. The employment effect on this group varies little across metropolitan areas in California and Texas and is nearly zero in most cases.

To the extent that wages and job opportunities of the native born are influenced by low-skill migrants from Mexico, females and especially Mexican ancestry females bear the impacts. However, these effects are not great even in areas with high concentrations of foreign-born, low-skill Mexicans. For example, in areas where at least 60 percent of the foreign-born population consists of low-skill migrants from Mexico, a 20 percent increase in this population reduces the real wage of native-born Mexican ancestry females by 1.27 percent and their employment by 0.40 percent (Tables 6A and 6B).

As discussed above, native, low-skilled females (both Mexican and non-Mexican) and other foreign-born groups tend to suffer wage and employment decreases as a result of the 20-percent increase in foreign-born, low-skilled Mexican workers. Although the effects are quite small on average for metropolitan areas in California and Texas (around 1 percent or less), some areas of high foreign-born, low-skilled Mexican concentration display relatively large effects. For example, in Los Angeles, the wages of foreign-born, high-skilled workers fall by 3.4 percent while employment falls by 0.8 percent. In McAllen-Edinburg-Mission, TX, the wages of native, low-skilled, Mexican females fall by 4.0 percent, accompanied by a 1.3 percent reduction in employment.

A general presumption is that the two groups most likely to enjoy benefits due to migration from Mexico to the United States are the migrants themselves and their U.S. employers. However, because most models that focus on the U.S. impacts of immigration assume separability of labor and capital, as well as not incorporating capital explicitly in the empirical framework, empirical models typically do not allow any assessment of the returns to capital. In the Mexican Model described above, we explicitly introduce capital and therefore we are able to perform simulation exercises that relate to the return to capital.

In some detail, Appendix C reports the percentage change in the real rental price of capital due to a 20-percent increase in foreign-born, low-skill Mexican

labor. Among all of the inputs, capital is the clearest winner. In California areas in general the real rental price of capital increases by 0.82 percent, but the increases are somewhat larger in agricultural areas like Merced (1.66 percent), Salinas (1.68 percent), and Visalia-Tulare (1.43 percent). However, the largest increase (2.54 percent) occurs in Los Angeles. The average increase in the real rate of return to capital in Texas is 0.33, but for many areas close to the border the return is considerably higher (Brownsville—1.44 percent; El Paso—1.58 percent; McAllen-Edinburg-Mission—1.75 percent). Another border area that experiences a large increase in the rate of return to capital is Yuma, AZ (1.66 percent). These results provide confirmation that the U.S. owners of capital benefit due to low-skill migration from Mexico.

A model containing racial detail also was estimated and simulated.[24] This model, although containing no detail regarding migrants from Mexico, may nonetheless be simulated for areas of high concentration of low-skill migrants from Mexico. These simulations indicate that a 20-percent increase in low-skill foreign-born labor in the Los Angeles MSA would reduce the real wages of low-skill native black females by 4.5 percent and result in a job-displacement effect of 4.25 percent for them. Low-skill native black males would experience a 3.4 percent job displacement effect. The low-skill foreign-born group itself would suffer a 3.4 percent real wage decline and 2.2 percent job displacement effect.

In summary, labor market impacts are the most intensively studied effects of the foreign born in the United States. Although these effects may be mitigated or reinforced through less-highly studied channels of influence, the following conclusions have the strongest support. First, in both 1980 and 1990 the foreign born had a tendency to put downward pressure on the wage rates of the native born and a tendency to displace them from their jobs, but the effects were not large at the national level. The Mexican-born had similarly small impacts at the national level. Second, the foreign born are highly concentrated regionally, and although internal migration and trade tend to distribute the consequences over broader regions, the economic consequences also are concentrated. The largest impacts of low-skilled migration from Mexico are on other low-skilled migrants from Mexico, because the two groups are good labor market substitutes. In areas of high concentration of new migrants from Mexico, such as El Paso, other migrants from Mexico suffer job displacement and significant downward pressure on their wage rates. Such effects impede the upward economic mobility of less-skilled migrants themselves. Third, in certain regions of foreign-born concentration, minorities appear to suffer job displacement and downward wage pressure. This effect is especially important in Los Angeles, where less-skilled African-American women bear the most noteworthy impacts. Finally, owners of capital and land are the primary U.S. beneficiaries from the presence of less-skilled migrants from Mexico.

Labor Market Impacts of Undocumented Migrants

The widespread belief that undocumented migrants depress the labor market prospects faced by unskilled native workers also has been debated in the academic and policy literature. Proponents of this view often argue that undocumented migrants compete primarily with low-skill native-born workers, particularly minorities and young workers, but there is quite a diversity of opinion about the magnitude of the effects. For example, Huddle, Corwin, and MacDonald (1985) estimate a 65 percent rate of job displacement or, in other words, for every 100 undocumented aliens working, 65 jobs are taken away from natives. However, many other researchers (e.g., Bean, Telles, and Lowell, 1987; Giffen, 1992) argue that the available evidence does not support the popular perception of substantial negative impacts on native workers due to the presence of undocumented migrants.

The United States General Accounting Office (GAO) (1986, 1988) prepared two companion documents relating to the economic effects of illegal alien workers in the U.S. based on studies extending through the mid to late 1980s. The 1986 report admits that knowledge about undocumented workers was mostly based on Mexican workers in the Southwest. The study concluded that, "although information is limited, illegal workers appear to displace (or take jobs away from) native or legal workers" (1986:17-18). GAO's 1988 report focuses on case studies in specific industries and localities, and not surprisingly, finds that there was substantial evidence of labor market displacement of native and legal workers by undocumented migrants. Such evidence raises questions about the possibilities for reconciling conclusions based on econometric modeling (which conclude that migration has benign displacement effects) and case study methodology (which concludes that substantial displacement effects can be attributed to migrants in specific industries and regions).

The final issue examined in the 1988 GAO report is whether the presence of undocumented workers is associated with a declining business environment. Although the report never actually defines what is meant by a "declining business environment," the term appears to refer to industries with shrinking employment. Using case studies to address the question, the report concludes that little or no evidence indicates that undocumented aliens concentrate in industries that are declining. Several case studies suggest that certain activities could not have been maintained in the U.S. without the availability of legal or undocumented migrant workers.

Using a simulation exercise in much the same way as Johnson (1980) did to study the effects of immigration, Grossman (1984) develops and simulates a model of undocumented migration to assess its effects on domestic employment. Her model assumes two sectors and three factors, domestic skilled labor, domestic unskilled labor, and undocumented migrant labor. The main contribution of the Grossman

paper, given her assumptions, is in showing that the sectoral distribution of undocumented migrant labor ultimately determines the impact of undocumented migration on the wage rates of domestic unskilled labor. That dramatic differences exist in the regional concentration of migrants and in the interindustry distribution of undocumented migrants implies distinct effects across regions. Because of their sources and border entry points, undocumented migrants may be even more concentrated than the legal immigrants, and their impacts will be concentrated accordingly.

Advances in methods for estimating the number of undocumented migrants have made it possible for Bean, Lowell, and Taylor (1988) to conduct a more direct test of the impacts of undocumented workers on native workers. These authors found that undocumented workers exert little impact on the earnings of natives in each of the other five labor force groups. Furthermore, the earnings impact of undocumented workers on domestic workers, when significant, more often was positive than negative. These authors conclude that the findings of small complementary effects between undocumented Mexicans and some native-born groups, together with the substitution effects found with legal immigrants, are more consistent with the notion that undocumented migrants hold jobs that natives avoid than with the view that undocumented migrants directly compete with natives for jobs.

Using the same procedure as Bean, Lowell and Taylor to estimate the number of undocumented Mexican workers, Taylor et al., (1988) also attempted to identify the labor market impacts of undocumented and legal Mexican migrants on the wages of workers in southwestern SMSAs. Despite the differences in methodology, the findings are very similar to those of Bean, Lowell, and Taylor. They conclude that the relative size of the undocumented population is positively associated with the wages of native males, except for native black males (for whom negligible effects emerged). On the other hand, legal Mexican immigrants have a small negative impact on the wages of native non-Hispanic white males and U.S.-born Mexican-origin males.

Industry and Occupation-specific Impacts

The aggregate supply of unskilled labor may be quite inelastic. Although the aggregate demand for such labor is elastic, conditions may be considerably different in specific industries, or occupations, or regions. Consequently, even though the effects of immigrants on total employment of unskilled persons and on their national average wage may be small, the effects on workers at a subnational level could be considerable. Offsetting redistributions could occur either across regions or across specific industries, such that the "net" effect of immigration will be a tiny fraction of the corresponding national total employment, and its consequences obscured from an aggregate perspective.

Even in areas where immigrant concentration is high, the local effects of immigrants may be quite difficult to measure due to various forms of arbitrage. One way for such arbitraging to occur is through internal migration. For example, if immigrants cause native wages to fall or displace native workers from jobs, the natives may out-migrate from areas where immigrants locate, which in turn may cause native wage rates to rise in the area of out-migration, and to fall elsewhere. Moreover, unemployment rates in areas of native out-migration fall, whereas they rise elsewhere, at least in the short run. Filer (1992) has described how areas with high immigrant concentrations become less desirable for natives, thereby triggering native out-migration.

The many industry case studies are largely descriptive, but taken as a whole, generate several insights about the complementarity and substitution issue. First, in certain industries located in specific regions, such as Los Angeles and New York, employment displacement effects of migrant workers are clearly evident. This is consistent with the conclusion of the 1988 GAO study of undocumented migration based on case studies. These negative impacts are frequently experienced by earlier cohorts of immigrants, but native-born workers also suffer job displacement. The displacement may occur because the ready supply of immigrant workers places downward pressure on industry wage rates in regions with heavy concentrations of immigrants, which in turn causes native-born and earlier immigrant workers to withdraw their labor services from the industry. A shortcoming of the case studies is that they are too narrow to trace the ultimate outcomes for native workers, who presumably find new jobs, but at considerable cost. Alternatively, the displacement may occur without any noticeable downward pressure on money wage rates, but rather because employers *perceive* new migrants to be more efficient workers. This perception of greater efficiency may reflect immigrants' willingness to work harder, to accept lower fringe benefits and less job security, and to resist unionization.

Another theme that repeatedly emerges from the industry studies is that employers find immigrant hiring networks to be advantageous. This observation is relevant in many sectors, such as agriculture, manufacturing, construction, and services. No study has systematically analyzed why these networks are advantageous, but several have inferred that relatively substantial cost savings must be realized through the use of network hiring. Employers save the cost of recruiting workers because no advertising is necessary when information about job availability is passed through the network by word of mouth. Moreover, especially when the networks consist of families, some informal training may occur before the migrant actually begins working. Informal social controls on worker behavior (e.g., attendance, work effort and resistance to unionization) may also be exercised through migrant networks. As such, migrant networks serve as informal screening devices that deliver reliable employees.

Using 1990 census data for 65 rural California towns, Taylor and Martin (1996) show in the context of a simultaneous-equations model that every 100-person increase in farm employment attracts 143 additional immigrants and results in 132 additional poor residents and 69 more welfare recipients. The increase in cash assistance accrues not so much to the new migrants as to residents and settled migrants, and the immigrants do not appear to be attracted by the availability of welfare. Their basic point is that California growers pay poverty-level wages, but receive a "welfare subsidy" in the sense that their workers require and receive public welfare in order to make ends meet. Indeed, this welfare subsidy amounts to $987 per California farm job, or 13 percent of farm worker earnings.

Region-specific Impacts and Internal Migration

The regional concentration of the foreign-born population has direct implications for an assessment of economic impacts. However, labor and capital flows along with interregional trade may arbitrage many differences, and thus diffuse the local impacts nationally. In general, empirical evidence appears to indicate that in areas where immigrant concentrations are particularly high, such as along the southwestern border, wage depression and job displacement effects are evident. These impacts are strongest among the less-skilled and lower-income prior migrants in these regions. Although the early evidence of such regional effects was based on data from the 1980 census, more recent models based on the 1990 census show the same tendencies, as indicated in Tables 6A and 6B.

With respect to U.S. internal migration, several studies have tried to disentangle the relationship between population growth and employment growth by asking: Do people follow jobs, or do jobs follow people? Are the two variables jointly determined or perhaps independent of one another? Various researchers have developed measures of the migrant attractive power of an incremental job and of the number of jobs induced by an additional (employed) migrant (Muth, 1971; Greenwood, Hunt, and McDowell, 1986). Whether based on cross-sectional or temporal data, the studies have generally found that jobs and migration are jointly determined. Such estimates have naturally kindled interest in the differential attractive power of jobs for internal versus international migrants, and in the differential number of jobs induced by each type of migrant. Unfortunately, no study provides convincing evidence on this issue.

Internal migration may be important in another, more subtle way. Filer (1992) suggests that to the extent that immigrants and natives are labor market substitutes, the location of immigrants in various areas will place downward pressure on the wage rates of natives, some of whom will also be displaced from their jobs. In turn, natives will out-migrate from such areas and others who might otherwise have in-migrated will not do so. Although Filer does not mention this possible cause of

native out-migration, immigrants may not only drive down local wage rates, but may also drive up rents, with the consequence that native out-migration rises and native in-migration falls. Because few studies show strong impacts of immigrants on native wage rates, the primary mechanism through which out-migration is triggered may be rising rents.

An important implication of Filer's results is that capital is attracted to areas where immigrants settle because of the wage depressing effects they have. The inflow of capital coupled with the net out-movement of native workers places upward pressure on the wage rates of local natives. On the other hand, the net in-flow of native workers to areas with few immigrants, coupled with slower rates of capital accumulation in these areas, puts downward pressure on wages in these other localities. The net result is that native wages are equalized across areas, and the impacts of immigration are arbitraged across the nation. Because the effects of immigration on native wage are spread thinly across the country, they are difficult or impossible to detect empirically, which helps to explain why immigrants repeatedly appear to have little impact on native wage rates. It is unclear how much time is required to arbitrage the economic effects of immigration, and no study has examined this issue carefully.

Filer's empirical results and interpretation have not gone unchallenged. Butcher and Card (1991) argue that if New York, Los Angeles, and Miami, the three most immigrant-intensive cities in the United States, are separated out, "native in-migration flows during the 1980s were actually positively correlated with inflows of recent immigrants" (p. 294). Greenwood and Hunt (1995) provide a mechanism to explain how the settlement of immigrants in certain areas could also attract rather than repel natives. Even if immigrants and natives are substitutes in production, immigrants may positively affect local labor demand through the wealth they bring with them, by encouraging area exports, and through still other channels of influence. Greenwood and Hunt's simulations suggest that the negative effects on wages due to substitution of immigrant for native workers are largely offset by these other channels of influence. Indeed, under reasonable assumptions, immigrants may positively influence the wages of natives, which would cause in-migration of native workers to areas where immigrants settle.[25]

The idea that internal migration is an important mechanism through which the effects of immigration are arbitraged across the country is intuitively appealing. However, at least on its surface the argument appears to assume that immigration is of a one-shot variety, similar to the Mariel Boatlift of Cuban refugees into the Miami labor market during the early 1980s. If this were the case, over a period of time internal adjustments would likely occur to spread the effects more widely.[26] A large body of research on regional adjustments suggests that the effects would not necessarily be spread very rapidly. Still more troubling for the arbitraging hypothesis

is the observation that new immigrants continue to settle in the same places as their predecessors. Due to lags inherent in the adjustment process, the continuing inflow of new immigrant arrivals should keep the direct impacts of immigrants relatively high in areas of immigrant settlement. The validity of the arbitrage hypothesis therefore rests on the speed of regional adjustment to equilibrium.

Relative to other foreign-born groups and relative to the native born, persons born in Mexico have relatively low rates of U.S. internal migration (Greenwood, Henning and McDowell, 1997). Indeed, the native born of Mexican ancestry have low rates of internal migration in general. For example, among those household heads born in Mexico who entered the United States between 1970 and 1974, only 4.1 percent made an interstate move between 1985 and 1990. During the same period 5.2 percent of native-born heads of Mexican ancestry made such a move. In contrast, the same entry cohort from other countries of origin had much higher rates of internal migration over the 1985-1990 period. Representative rates of internal migration for these other groups are as follows: Philippines, 12.3 percent; Germany, 18.0 percent; United Kingdom, 19.7 percent; India, 21.7 percent; Korea, 15.8 percent; and Vietnam, 15.2 percent. Among these countries, only for Mexico do the foreign born have lower rates of internal migration than the native born of each respective ancestry.

Neuman and Tienda (1994) also confirmed that undocumented migrants from Mexico are less likely to move across state lines than undocumented migrants from other regions. An analysis of administrative records (Legalization Application Processing System, or LAPS) revealed that just over one-quarter of amnestied immigrants changed residence at least once between the time of most recent entry and application for amnesty, but the likelihood of inter-state moves as undocumented migrants varied by place of birth. Mexicans were least likely to move subsequent to their initial entry while Asians and Africans were most likely to do so. Specifically, only 19 percent of undocumented Mexicans who applied for legal status had moved across state lines before soliciting amnesty compared to over two-thirds of undocumented migrants from Asia and Africa, and over half of undocumented migrants from other Latin American countries (except Salvadorans, whose interstate migratory behavior was similar to that of Mexicans).

If secondary migration leads to greater residential dispersion throughout the country, the social impacts of undocumented migration ultimately will be less severe in the states that serve as gateways for initial entry. Overall, unauthorized Mexican migrants who moved across state lines were less residentially concentrated at the time of application for amnesty than were nonmovers. For Mexicans, California and Texas were the main gateways for unauthorized entry. However, there was limited evidence of dispersal of impacts through inter-state moves of unauthorized Mexican migrants; nonmovers were more than twice as likely as movers to have

entered through California (three out of four nonmovers from Mexico entered through California compared to just over one-third of movers). Mexicans who entered without inspection through Texas were more likely to have changed their state of residence by the time of application for amnesty, thereby attenuating impacts in this state. Specifically, just over half of Mexican movers entered through Texas compared to more than one-fifth of nonmovers.

These low rates of internal migration among persons born in Mexico are due to many factors, such as relatively low levels of education, lack of English language skills, and strong ties to areas with high concentrations of persons born in Mexico. Like education, migration is a form of investment in human capital and as such migration presumably yields higher future returns. Historically, internal migration has been a mechanism through which Americans have taken advantage of employment and wage opportunities elsewhere to improve their economic status. Thus, the low internal migration rates of both those born in Mexico and those born in the United States of Mexican ancestry may restrict their access to areas that provide favorable economic opportunities. Lack of internal mobility also perpetuates high concentrations of the Mexican-born population. The continued entry of migrants from Mexico who are good labor market substitutes for earlier migrants results in continued job competition between the groups, which in turn restricts wage growth for them.

International Trade

Most empirical studies of the economic consequences of U.S. immigration have failed to consider the international trade side. However, an exception is Borjas, Freeman and Katz (1992), who attempted to carefully assess the labor-market consequences of both immigration and trade. They first show that international trade had a significant implicit effect on the labor market and that this effect changed dramatically during the 1980s relative to the 1960s and 1970s. Indeed, the trade deficits of the 1980s resulted in a considerable increase in the implicit supply of low-skill labor to the manufacturing sector, which is the focus of their attention.

Borjas, Freeman and Katz (1992) conclude that both trade and immigration have greatly increased the effective supply of high school dropouts and that trade and immigration flows may have contributed substantially to the poor labor market performance of the least educated American workers during the 1980s (1992:240). More specifically, they argue that the various changes in relative skill endowments due to the combination of trade and immigration can explain over 40 percent of the decline in the relative earnings of high school dropouts during the 1980s (p.240). These findings indicate a significant impact of trade and immigration on some of

the most disadvantaged U.S. workers. However, the separate effects of trade and immigration, which in an important sense are not causally independent, are not measured.[27]

Conclusions on Labor Market Channels of Influence

Do low-skill workers from Mexico place downward pressure on the wage rates of other U.S. workers and displace them from their jobs? Analyses based on data from the 1980 census concluded that immigrants have little impact on native workers, except in areas of high immigrant concentration. In such areas some job displacement and slight downward pressure on wages was evident, but the largest impacts were on the migrants themselves. Moreover, in sectors where immigrants concentrated, evidence from case studies suggested some job displacement for natives.

The major surge of international migration that occurred during the 1980s has raised questions about the validity of conclusions based on 1980 data. Moreover, earlier economic models did not concretely address the impacts of migrants from Mexico on various skill classes of U.S. labor. Data from the 1990 census generally support the conclusions based on earlier data. Specifically, migrants from Mexico have little impact on native workers. Only limited evidence points to job displacement of natives and then mainly in areas of high concentration of Mexican migrants. Case studies continue to indicate the displacement of native workers in sectors that attract foreign workers. Where the migrants are more concentrated, the effects on the wage rates and employment of native workers, especially females of Mexican ancestry, are slightly negative, but even in these areas large increases in low-skill workers from Mexico have little impact on native workers.

One exception is that in Los Angeles the migrants displace low-skill black females and put downward pressure on their wages, and they also tend to displace low-skill black males. The largest labor market impacts of low-skill migrants from Mexico are on other such migrants from Mexico, because the current and earlier migrants are very good labor market substitutes. In areas of considerable concentration of these migrants, the negative effects on the wages and employment of earlier migrants are large, which appears to discourage upward wage mobility for these newcomers to the United States. The continued flow of new migrants and their location in the same areas as their earlier counterparts, coupled with relatively low internal migration rates of persons born in Mexico, suggest that migrants from Mexico will have some difficulty in improving their economic status, at least relative to other foreign-born groups.

Impacts through Economies of Scale

An increase in population ordinarily requires an increase in services provision—education, police protection, health care, electricity and sewer service to name a few. In the case of these common services, the pertinent question from the standpoint of impacts is whether the additional services are provided at increasing or decreasing marginal cost. Studies of the fiscal impacts of immigration usually assess the costs of immigrants on particular services by calculating the total amount spent on the service and dividing that by the number of persons who use the service. This procedure yields an average cost for a particular service for a designated administrative unit. The problem is that many studies assume that the marginal costs are equivalent to average costs. Under some circumstances marginal costs are lower than average costs; under other circumstances, marginal costs are greater than average costs.[28] Scale effects are an important reason why these relationships are variable, but most studies of the fiscal impacts of immigration assume equivalency of marginal and average costs, which we discuss further in the section on fiscal impacts.

Services like sewage, utilities, and roads can be more cheaply provided in areas of higher population density. Rural electrification is much more expensive, per capita, than urban electrification. Rural school districts may spend less per pupil than urban districts, but it is difficult to account for possible differences in quality of the educational services provided. As Preston (1989) notes, the distribution of people in the United States, with very high concentrations in large metropolitan areas and very low population densities in other areas, is precisely the kind of population distribution required for positive returns to scale. If there were constant or decreasing returns to scale, population density would be more uniformly distributed across the U.S. mainland, thus minimizing the local scale economies affecting the average person. That Mexican immigrants are densely settled in a few large cities of the Southwest and Illinois implies clear economies of scale.

If there are in fact positive returns to scale, the implication for immigration is fairly clear: more people make the whole society more efficient, and immigration would therefore inevitably be a benefit to the host society. The issue is, of course, more complex because there can also be diseconomies of scale, and because the extent of positive or negative returns to scale is the subject of substantial disagreement in the empirical literature. The question of returns to scale is central for assessing the impacts of Mexican immigration, which is distinguished by its volume relative to other country-specific flows, and its high concentration in a few large cities.

Pro-immigration analysts generally assume a positive return to scale for population growth. Most anti-immigrant work emphasizes over crowding, excessive

consumption of limited resources, and other implicit negative returns to scale for population growth. The economic literature that employs explicit models for the impacts of immigration, such as Borjas (1995), almost invariably assumes constant returns to scale in the production functions. Measurement of real returns to scale presents many problems mainly relating to the empirical problem of measuring returns or output or services in units of constant quality, and mathematically working with such models. However, this common assumption tends to bias conclusions about scale effects against some of the possible economic benefits of immigration. Kuznets' economic history of the United States makes a strong case for the importance of increasing returns to scale over time, and other authors have pointed out that there is little reason to believe these historical arguments are any less relevant today.

One clear example where scale effects may be strongly positive and where there is a paucity of economic research is in the multiplier effects via consumption and production associated with the proliferation of densely settled ethnic neighborhoods. Sociological studies have been more diligent in studying the growth and development of ethnic business economies in specific locations and for specific groups (e.g., Cubans in Miami and Koreans in various urban settings). However, the vast majority have ignored business ownership patterns among Mexican immigrants despite their dense settlement patterns. Two reasons explain this relative neglect. First, Mexicans have very low education levels which are presumed too low for a substantial impact on business ownership; second, census data show very low rates of self-employment among Mexicans relative to other immigrants.

There are reasons to challenge the idea that business ownership will remain low among densely settled Mexican immigrants. Although much of the economic literature assumes that years of schooling directly measures skill and hence worker productivity, the labor market profile presented above revealed some anomalies in this relationship. Especially noteworthy is that Mexican immigrants complete appreciably lower levels of education than U.S.-born blacks yet have higher rates of labor force participation. One possible reason for this outcome is that Mexican immigrants are preferred workers to native blacks, particularly in inner city labor markets where both groups come together and compete for low wage jobs (Wilson, 1996; Tienda and Stier, 1996; Tienda, 1989). Another reason is that Mexican immigrants find alternative ways of earning a livelihood, including informal employment and self-employment (Tienda and Raijman, 1996; Raijman, 1996). The latter option, which appears to be associated with residential concentrated settlements and thereby economies of scale, has been relatively ignored by students of Mexican immigration.

Entrepreneurship among Mexican Immigrants

Julian Simon (1989) argues that immigrants bring with them knowledge based on the experience of how things are done in other places and may therefore be highly productive and predisposed to self-employment even with a limited formal education. A corollary to Simon's argument about working-class innovation and entrepreneurship is the literature on immigration that treats immigrants as self-selected for entrepreneurial spirit and work ethic. Presumably, the possibilities of business formation among relatively unskilled Mexican migrants would be greater in ethnic neighborhoods where demand for goods and services that cater to Mexican tastes and preferences would generate demand for ethnic business concerns.

Although residentially concentrated, Mexican migrants have relatively low rates of self-employment and business ownership (Borjas, 1986; Portes and Bach, 1985), particularly by comparison to migrants from Cuba and Korea. Surprisingly, this anomaly has produced few studies to explain why this is so. However, a recent study of business activity in Little Village, one of Chicago's two Mexican migrant communities, showed much higher levels of self-employment among Mexican migrants than revealed by conventional census data.[29] This is because much self-employment activity is informal, and because self-employment activities were vastly under-reported, especially by individuals whose self-employment activity was pursued in addition to jobs in the formal labor market. The unique design of the Little Village study, which involved both a representative household survey and a random survey of extant businesses, permitted a detailed inquiry into the determinants of business formation among Mexican migrants. Rather than studying existing businesses (as most studies have done), the design provided information about individuals at different states of business formation. Finally, the study design permitted a comparative perspective about how and why different ethnic groups access the world of business ownership.

Findings based on the 1994 household and business surveys in Little Village challenge assertions of low entrepreneurial disposition among Mexican migrants on several grounds. First, the study revealed that the level of potential self-employment in the community is extremely high. Half of the population of Little Village aspired to starting their own business and of these, one in three had taken some concrete steps to actualize their goal. Both financial capital and lack of information about requirements to establish a formal business inhibited the likelihood of business formation for aspiring businessmen. The household survey also revealed that respondents inclined to begin a business differed systematically from those not predisposed to do so in their risk-taking disposition, in their family links to business, and in their economic resources. Results also confirmed that residence in environments where ethnic businesses proliferate is conducive to demonstration

effects and sources of financial and nonfinancial support that puts business ownership within the reach of individuals with modest education levels and limited resources. Thus, scale effects associated with densely settled neighborhoods appear to be conducive to enterprising activity even among low-education Mexican migrants.

A second major finding of the study is that the invisibility of Mexican self-employment, as reported by conventional census data, stems from the inability of current reporting categories to include informal activities and multiple job holding. Specifically, by neglecting a variety of informal activities (such as street vending, house repairs and child care services) that figure prominently in the income packaging strategies of migrant families, rates of self-employment of Mexican migrants (especially women) are seriously under-reported. The Little Village study also showed that the majority of self-employment activity among Mexican migrants residing in Chicago is marginal and results in response to the precarious labor market status of this migrant group. Informal self-employment provides income for migrants whose social circumstances, namely low education or undocumented status, limit their access to paid jobs. Dense settlement patterns also are conducive to the emergence of informal activity that caters to the needs of other co-ethnics.

A third major finding from the study concerns the heterogeneous ethnic composition of the business community in Little Village, which serves a relatively ethnically homogeneous Mexican neighborhood. During the last decade or so, various ethnic groups (notably Koreans, Arabs, Chinese, Vietnamese and Pakistanis) joined the white and Mexican business owners in Little Village. These groups differ notably in their prior entrepreneurial experiences in ways that Simon (1989) indicated. Specifically, Mexican business owners in Little Village had less experience in the world of business than other ethnoracial groups who owned and operated businesses in the neighborhood. However, Mexican migrants' experience deficit was compensated by the distinct pathways to self-employment along ethnic lines. For them, the informal economy served as a pathway to business ownership while entry through employment in a co-ethnic firm is more common among Koreans. That is, most Korean immigrants who owned and operated a storefront in Little Village acquired their business know-how by working in similar firms owned by co-ethnics, but nearly one-in three businesses owned and operated by Mexican migrants began informally. Lacking a strong ethnic economy to acquire training and skills, as do Koreans and Cubans, for example, many Mexican migrants use the informal sector as a means of acquiring skills and capital needed for starting a business in the formal sector. Informal economic activities allow enterprising migrants to experiment and explore the viability of particular types of businesses. By testing the market, possibly accumulating capital or learning about its availability, and acquiring rudimentary skills in a particular

line of work, informal self-employment serves as a steppingstone to successful business formation.

Conclusions on Impacts through Economies of Scale

Although relatively understudied in the literature on impacts of Mexican immigration, economies of scale (generated by the emergence of dense Mexican immigrant communities) can produce positive economic outcomes. The Little Village study showed that dense settlement patterns are conducive to the emergence of informal economic activity that caters to the needs of other co-ethnics. Some of this activity eventuates into formal businesses because many Mexican immigrants acquire business-relevant experience through informal market activities. Thus, scale effects associated with densely settled neighborhoods appear to be conducive to enterprising activity even among low-education Mexican immigrants.

Additional scale effects derive from the fact that Mexican immigrants consume goods and services produced in the United States, thereby contributing to aggregate income growth (although the net beneficiaries of immigrant consumption are the owners of capital). There is relatively little study of the consumption profiles of Mexican immigrants. This information is essential for appreciating how the scale effects of Mexican immigration operate through demand for goods and services, including those produced within and outside of ethnic labor market niches. This is an important area for further research because it would help balance the preponderant focus of impact studies on costs by acknowledging that many positive impacts are generated through increases in aggregate demand or expansion of local labor markets.

Welfare Participation

Prior Studies

One line of research conducted at the national level that has important implications for fiscal impacts (as well as perceptions about the costs and benefits of immigration) focuses on immigrants' use of social services. These studies are largely based on census-type data and attempt to "explain" differentials in program participation by immigrant and native families, emphasizing how eligibility characteristics unequally dispose families to participate in means-tested income transfer programs. *A main conclusion from the various studies of public assistance utilization is that immigrants in general are not more prone to use public assistance than natives of similar socioeconomic characteristics.* If controls for various demographic and family characteristics are not included in the analysis, then immigrant-to-native comparisons differ, depending on the gender of the head of

household (Blau, 1984), race/ethnic group (Tienda and Jensen, 1986, and also Jensen, 1988), and the year of analysis (Borjas and Trejo, 1991, and Borjas, 1995b).

For example, for male headed households, Blau found that immigrant families were more likely than native families to participate in a welfare program, but the opposite obtains for female headed households. Borjas (1995b) shows that immigrant families' welfare participation rate has risen in recent years. Concerning various race/ethnic groups, and Hispanics in particular, a higher percentage of Hispanic immigrant families than native Hispanic families are found to receive public assistance if controls for other characteristics are not included in the analysis.

Recent research has focused less on the issue of direct immigrant-to-native comparisons, and more on whether immigrant propensities to use social services have changed over time and/or whether the propensities of more recent cohorts differ from those of earlier cohorts. This research has also considered how years since migration has an impact on the utilization of public assistance programs. On the one hand, many individuals have argued that the economic assimilation that occurs with longer U.S. residence should result in higher incomes, thus reducing the use of public assistance. However, additional U.S. experience also results in greater knowledge of and familiarity with social programs, thus conceivably increasing the receipt of public assistance. The early evidence concerning this issue is especially mixed. Studies using a single cross-section of data (e.g., Blau, 1984, and Tienda and Jensen, 1986) were generally unable to find a consistent pattern linking length of U.S. residence and the probability of receiving welfare. These analyses do not allow the impacts of U.S. residence to be distinguished from entry cohort effects. The various works by Borjas provide the strongest evidence indicating that the use of public assistance rises with length of U.S. residence, but these conclusions are based on the strong assumption of uniform period conditions across groups. Jensen also finds some evidence that years in the U.S. increases welfare utilization, but this evidence does not separate cohort and assimilation effects.

Concerning the relative propensities of different cohorts to use public assistance, Borjas and Trejo as well as Borjas (1995b) find that the most recent cohorts have higher propensities to use the welfare system than earlier cohorts. They generally attribute this finding to the shift in natural origin mix of the immigrant flow. Jensen finds similar evidence for white immigrants, but he is unable to link the higher use of welfare by Asians in 1980 to a higher utilization propensity by the recent immigrants. Moreover, recent Hispanics were not found to have higher use in 1980. In fact, recent Mexican immigrants actually appear to have a lower probability of receiving transfer payments in 1979. Thus, Jensen (and also Jensen and Tienda) find differences across immigrant groups as well as differences within groups. Such potential differences across and within immigrant groups are not specifically addressed in the either the Borjas and Trejo or the Borjas analyses. Moreover, the

methodology used by Borjas and Trejo (and also Borjas) constrains the period effects on welfare participation by immigrants to be identical to those of natives. Evidence presented by Jensen raises questions concerning the appropriateness, and consequently the impact, of this restriction. All prior studies are limited because their reliance on 1980 data means that "recent" immigrants arrived over 15 years ago. Much has changed in the U.S. welfare policy climate since then.

Participation by the foreign born in welfare programs is the focus of considerable scrutiny in the United States. Presumably motivated by the notion that legal and unauthorized immigrants participate in some sense "too much" in such programs, Congress passed the Personal Responsibility and Work Opportunity Reconciliation Act of 1996. This Act restricts the access of even legal immigrants to welfare utilization. In spite of the passage of this legislation, many questions regarding immigrant utilization of public assistance programs remain only partially answered or unanswered. Precisely which public assistance programs are used relatively much by which entry cohort of which foreign-born group relative to which native-born group? The answers remain obscure. Accordingly, in a paper prepared for the Commission (Davies and Greenwood, 1997), we provide an unusually detailed analysis of public assistance utilization by Mexican-born households relative to various control groups of native-born households.

1990 Welfare Participation

This analysis uses the 1990 Public Use Microdata Samples to analyze participation in means-tested programs by Mexican-born households who resided in the United States. Several control groups are explored, as are several subsamples of the data, in order to provide a more complete analysis of welfare participation differences between Mexican-born and native-born households. Separate analyses of young and senior age groups for various nativity and ethnic subsamples permitted us to approximate program participation differences due to AFDC and SSI. The empirical results of this study indicate that Mexican-born households are no more likely to use welfare than either otherwise comparable native-born households of Mexican ancestry or otherwise comparable native-born households in general. However, they are more likely to participate than native whites, but less likely than native blacks. Moreover, recent cohorts from Mexico are less likely to use welfare than any control group, whereas more distant cohorts are more likely users.

Similar results obtain when households are partitioned into those headed by females and those headed by males. The highest incidence of welfare usage is among single female-headed households, but Mexican-born females in this group are significantly less likely to participate in welfare (AFDC) if they entered the United States in recent cohorts. This finding holds relative to different control groups, and it

holds as well for young female household heads (less than 30 years old) born in Mexico. The same general finding holds for male-headed households from Mexico, as well as for young male-headed households from Mexico. Recent entry cohorts participate less in welfare (AFDC) than otherwise comparable households both of Mexican ancestry and of all natives. However, Mexican-born male-headed households 65 years old and over who entered the United States in more distant cohorts show some tendency to use welfare (SSI) significantly more than otherwise comparable native-born households of Mexican ancestry. Although a similar relationship holds relative to all native households 65 and over, it is less strong.

Borjas and Trejo (1993) concluded that immigrants assimilate into welfare. Findings of the present study do not directly address the assimilation issue because we do not employ two censuses to form synthetic cohorts that are followed through time. However, results from the Davies and Greenwood study suggest some caution in drawing conclusions regarding the assimilation of Mexican immigrants into welfare. When they are young, recent entrants in the United States, the Mexican-born population is less likely to use welfare, which is almost certainly AFDC. When they grow older, or enter at older ages, they are more likely to use SSI.

In studies of this type, where the foreign born are analyzed relative to a control group of native-born households, investigators may impute behavior to the foreign born when the native-born control is in some sense more responsible for a finding. The apparently higher use of SSI by the Mexican-born population is almost certainly due to their not qualifying for Social Security during their retirement years. The control group of natives has Social Security income available to it, which in turn lessens its reliance on SSI. Indeed, it is not clear whether the results of the present study are due to the lesser use of SSI by older natives or the higher use of SSI by older persons born in Mexico.

Finally, it is important to note that, while there is a general consensus that immigrants are not more prone to use public assistance than natives of similar socioeconomic characteristics, immigrants' characteristics determine their eligibility for welfare and, to a large extent, their propensity to accept means-tested income transfers. For instance, Mexican immigrants to the United States are characterized by low levels of educational attainment, large families, and poor English-language abilities. All these factors, among others, are generally found to be positively related with the level of welfare use.

Conclusions about Welfare Participation and Implications of Recent Policy Changes

Migrants from Mexico to the United States tend to be young job seekers (second and third chapters). In general, they do not appear to cross the border in order

to enjoy welfare benefits, although a minority of past migrants may have been motivated by the desire to collect welfare.[30] Because they are primary-care providers to children, young females have considerably higher propensities to participate in U.S. welfare programs than young males, and among young females, those who are household heads with no spouse present have the highest propensities to use welfare. However, young females from Mexico were significantly less likely to use AFDC (in 1989) than either otherwise comparable native-born females of Mexican ancestry or otherwise comparable native-born females in general. The same conclusion holds for young female household heads with no spouse present. Household heads 65 and over who were born in Mexico were more likely to receive SSI in 1989 than otherwise comparable native-born heads, but this tendency may have been due to the failure of the Mexico-born heads to qualify for Social Security relative to their native-born counterparts.

Welfare participation patterns and their consequences will change as a result of recent changes in welfare legislation. The Personal Responsibility and Work Opportunity Reconciliation Act of 1996 defines a new eligibility category for legal aliens—"qualified aliens"—which includes lawful permanent residents, refugees, and asylees, as well as certain others. Most qualified aliens are barred from food stamps and Supplemental Security Income (SSI). Moreover, this law bars qualified aliens admitted to the U.S. before the law's enactment on August 22, 1996, from all means-tested federal programs for their first five years in the United States. States also are permitted to deny qualified aliens Temporary Assistance to Needy Families (TANF), which replaced Aid to Families with Dependent Children (AFDC), Medicaid, and various federally-funded state programs, such as child care and services for the elderly. Exceptions are made for refugees and asylees during their first five years in the United States. Naturalized citizens are eligible for benefits available to native-born citizens, but naturalization typically requires five years as a permanent resident alien.

Most federal public benefit programs have not been available to undocumented migrants, but the old law was silent on such eligibility for certain minor programs. The new law defines "not qualified aliens" to include undocumented migrants, and explicitly bars their use of federal public benefit programs as well as programs financed by state and local governments. If states wish to make benefits available to non-qualified aliens, they must pass a law that allows them to do so, which is highly unlikely.

The new eligibility requirements may discourage the entry of some potential migrants from Mexico. However, because most young migrants from Mexico seek better job opportunities in the United States and not welfare, we expect this effect to be small. Moreover, some potential legal migrants who would have been eligible for SSI under the old program may be discouraged from entering the United States

under the new, more restrictive eligibility criteria. Again, we expect this effect to be small since migrants from Mexico tend to be young and ineligible for SSI. With respect to migration from Mexico, the major effect of the new legislation may be the perception that the "climate" has changed and that the U.S. is less receptive to migrants from Mexico than previously. This perception may be particularly true for undocumented migrants.

A major limitation of prior studies of welfare participation is their failure to consider undocumented migrants because most studies of welfare participation are based on either 1980 or 1990 census data. Census data enumerate all foreign-born individuals residing in the United States on a specific day, but do not permit distinctions among various types of migrants, notably legal resident aliens (immigrants), undocumented migrants, and temporary residents such as students and various types of visitors. However, because a large fraction of all undocumented migrants are young males born in Mexico, and because young males born in Mexico have relatively low welfare participation propensities, it is unlikely that undocumented migrants are heavy users of welfare. Finally, the new welfare reform legislation explicitly denies benefits to undocumented migrants, which guarantees far less participation by this population at the present time relative to 1990. Welfare officials disinclined (or disallowed) to query legal status of applicants in the past may be more inclined to do so in the future.

Welfare participation by the foreign born is usefully considered from two perspectives. The first is the perspective of the migrants themselves and the second is that of the levels of government that are responsible for providing welfare benefits. The migrants are clearly better off, at least in the short run, with welfare than without it, but the major point of contention concerns the current costs to society of providing welfare benefits relative to the tax payments made by the users and relative to future costs imposed on society (i.e., negative externalities) if it does not provide the benefits.

A major rationale for welfare provision is to avoid future costs to society that would be incurred if welfare were not provided. Thus, for example, school-lunch programs presumably promote healthier, more attentive children who will learn more, thereby enhancing their future employability, and discourage poor health (and future public health costs) and criminal activities (and future costs associated with such activity). A delicate balance exists between the withholding of current welfare from migrants and future costs that may be incurred on society if the benefits are not provided. Estimates do not exist for this aspect of the public balance sheet.

In spite of relatively low welfare participation by young migrants born in Mexico, we can not infer the absence of a negative impact from data on behavioral tendencies. Data relating to such tendencies indicate nothing about taxes collected

from these migrants nor the cost of providing welfare services to them. Thus, we now turn our attention to the broader question of the net fiscal impact of Mexican migration to the United States.

Fiscal Impacts

Among the various channels through which immigration exerts economic effects, the fiscal channel has commanded considerable attention in the past five years. The fiscal channel entails the cost of government services such as education, transfers and benefits provided to immigrants, along with other costs for such things as the incarceration of immigrant prisoners, minus the taxes and fees that immigrants pay. Moreover, on-going residents may experience either higher or lower taxes due to the presence of immigrants, but this potentially important effect has been largely ignored to date. As states have brought suit against the U.S. federal government to recover the costs of providing services to unauthorized migrants, an important debate has taken place over how to quantify the fiscal impacts they initiate, as well as the fiscal impacts of migrants from abroad in general. The political backlash against the foreign born, especially in California, has increased the need for careful scholarly attention to the issue (Smith and Edmonston, 1997). Because Mexican migrants, both legal and undocumented, are disproportionately concentrated in California, Texas and Illinois, we focus on these three states.

Principles of Agreement and Disagreement

The debate over the fiscal impacts of migration has generated relatively few points of consensus. Most recent studies seem to agree that immigrants, and especially undocumented migrants, impose a fiscal burden on state and local governments, but there is considerable disagreement about the magnitude of the fiscal deficit. Weintraub and Cardenas (1984) are a notable exception: they surveyed undocumented migrants in Texas, and estimated a state level net fiscal gain of between $120 million and $180 million per year.

At the national level there is less consensus, with some authors arguing that immigrants subsidize natives, and other authors arguing the opposite. The reasons for this disagreement are partly technical of course, but in large measure the technical questions stem directly from the more basic issues inherent in trying to measure the economic impacts of one demographic group on another when the two groups are substantially intermingled. Rothman and Espenshade (1992) and Vernez and McCarthy (1995) survey the literature on fiscal impacts and comment on the inherent difficulties (see also, NAS, 1996; Smith and Edmonston, 1997). Five of the most serious difficulties are summarized below.

Inaccurate Estimates of the Undocumented Population

INS and Census Bureau estimates of the undocumented alien population in the United States in 1992 ranged between 3.2 million and 3.8 million, a difference of 15 percent. In calculating their estimates of the costs of undocumented migration, the states used population figures that were almost 50 percent higher than Census Bureau's best estimates. In the simple simulation we present below, we compare results using the "best" estimates and the very highest estimates of the undocumented population. This exercise responds to the NAS (1996) recommendation to generate a range of fiscal impacts using different assumptions.

Difficulties in Partitioning the Foreign Born by Legal Status

Many households contain people whose migration and legal statuses differ. For instance, many of the children of illegal immigrants are themselves U.S. citizens because they were born in the U.S. Should the education of these children be "charged" to the fiscal account of the immigrants? Because public primary and secondary education is by far the most expensive local service that immigrant families consume, decisions about how to identify the children has an enormous consequences on the fiscal balance sheet. Moreover, the present value of this cost has to be discounted by the future value of the productivity of well-trained workers, and this may reverse the balance of this fiscal impact.

The Problem of Accounting Completeness

None of the known studies successfully account for all of the relevant costs and benefits. Some costs, such as schooling or incarceration costs, can be estimated by applying an average per-person cost to a fixed number of persons who receive the service. But other services, such as highway construction, defense costs and governmental debt service are more difficult to apportion. And while some studies, such as that by the Urban Institute (Clark et al., 1994), made an effort to quantify the tax payment rates of illegal aliens for some kinds of taxes, their payment rates for other kinds of taxes and fees are unknown. Moreover, depending upon the cost conditions under which various public services are rendered, the taxes paid by on-going residents could rise or fall, because public services are typically priced at average cost. Finally, quality deterioration could occur in public services, such as due to crowding in schools or due to special program requirements that spread already thin teacher resources over more children. The states' own estimates of the fiscal burden of illegal migrants have included only

the cost of services provided, without accounting for any revenue from the group. This accounting strategy produces a distorted balance sheet (GAO, 1994). Consequently, each of the fiscal impact studies represents an incomplete fiscal accounting, and each is incomplete in a different way because a slightly different set of services and taxes is estimated, and/or a different level of government is involved in the revenue and expenditure side of the ledger. Consequently, most results are not directly comparable.

The Problem of Average versus Marginal Cost

To assess the cost that the children of illegal migrants impose on a local school system, fiscal impact studies divide the total education budget by the total number of students in the system, and apply that average cost to the number of children of illegal migrants in the system. The problem with this strategy, which is the only practical methodology to use, is that marginal costs seldom equal average costs. That is, the cost of educating one additional child could be zero if classrooms and teachers were already in place and could readily accommodate the additional student. Alternatively, if the new student needed special instruction of some kind, or if a new investment in physical plant were required to accommodate the student, marginal costs could be higher than average costs. A related problem is that analyses are often performed at administrative levels that encompass highly variable mean costs. For example, Rothman and Espenshade (1992) criticize Simon's (1981) national level fiscal study for applying national average education costs and tax rates to all natives and immigrants, despite that the different residential distributions of the groups imply different average cost and tax regimes.

The Problem of Time Frame

Except for a few exceptions, such as Loveless et al. (1996), which employed a 10-year span of time-series data, all the fiscal impact studies examine a yearly budget. The problem with the yearly approach is that immigrant's cost/benefit profile is likely to change over the life course (as Loveless and his colleagues have shown), and therefore the annual budget is a poor basis for estimating even short-term impacts. The National Academy of Sciences (1997) also conducted a long-term analysis that used a recent set of annual calculations as a starting point and projected both revenues and expenditures into the future under various assumptions about the course of immigration and fiscal policy as well as the economic assimilation of immigrants and their descendants. We highlight the main findings of this study below, and also identify some of its limitations in our concluding section.

State-Level Fiscal Impacts

Despite the above caveats, which are crucial to understanding the limits of the fiscal impact studies, for the purposes of illustration we prepared a secondary analysis of the fiscal impact of undocumented migrants for three large states whose migrants are most heavily Mexican: California, Texas and Illinois.[31] The following analysis is based largely on data assembled by Clark et al (1994), which includes a thorough examination of how state-level costs and taxes can be measured, as well as an evaluation of the states' own estimates of fiscal impacts.[32] We made a few minor alterations to their figures in order to apply all per capita costs and expenses (in 1992 dollars) to the 1992 populations. The three sources of state and local revenue included in their study account for less than 50% of the revenue of each of the states, and the costs are also incomplete. Therefore, we cannot draw conclusions about the total fiscal impact. The costs included in the model are primary and secondary school education, the state portion of Medicaid costs, and incarceration costs in state and local jails. The revenue side of the model includes state income tax, sales tax and property taxes.

We have added data that allow for comparisons between estimates for the (incomplete) net fiscal costs of illegal migrants compiled by Clark et al. and the comparable net fiscal costs of the rest of each state's population. These data, broken into three different scenarios, are summarized in Table 7, with a more detailed breakdown available in Appendix B. Scenario A in Table 7 represents figures based on best estimates of the illegal alien population established by Clark et al. Because the fiscal picture is not complete, the 'net' aggregate fiscal impacts contain obvious anomalies, such as the total population of California running a $14 billion surplus with the state.

The aggregate cost estimates of Clark et al. are considerably lower (more than $1 billion less) than those generated by the State of California, largely because of the wide discrepancy in the estimated size of the illegal migrant population in that state. By comparison, Illinois has such a small undocumented population that differences in cost estimation yield fairly modest gaps in the assessment of the cost of providing services to the undocumented.

Useful comparisons can be made between the net fiscal impacts of the undocumented and the rest of each state's population, but it is important to bear in mind that the fiscal balance is incomplete, and that other unmeasured revenue streams and costs could conceivably offset these effects. In scenario A, illegal migrants in California use $1,124 of state and local services per capita, which is higher than the $906 per capita of state and local services that the rest of the population uses. Public school expenses account for about two-thirds of these costs. In Texas, the undocumented and the rest of the population both use somewhat more than $1,000 per capita in services, and school costs account for more than 80% of the costs. In

Table 7

Fiscal Costs and Benefits of Illegal Immigrants, Compared to All Other Persons in Three States, in 1992 Dollars

Scenario A: The best estimates of Clark et al.

	1992 Number of Persons	Total Costs (million $)	Costs per Capita ($)	Total Taxes (million $)	Taxes per Capita ($)	Net Burden (million $)	Burden per Capita ($)
California							
Undocumented immigrants	1,410,000	$1,585	$1,124	$755	$536	$829	$588
Natives, and documented immigrants	29,457,000	$26,676	$906	$41,933	$1,424	-$15,257	-$518
Total	30,867,000	$28,261	$916	$42,688	$1,383	-$14,428	-$467
Illinois							
Undocumented immigrants	173,000	$113	$652	$96	$556	$17	$96
Natives, and documented immigrants	11,458,000	$11,207	$978	$11,671	$1,019	-$464	-$40

See Text for discussion, and see appendix B for more detailed elaboration

Source: Based on Clark, Passel, Zimmerman and Fix (1994) and Statistical Abstract of the U.S.

Illinois, the undocumented use less state and local resources than the rest of the Illinois population (and less than the undocumented in the other states) for two reasons. Clark, et al. estimate that the age profile of the undocumented is older in Illinois and the high school dropout rate is higher for the undocumented there (see their Table 4.9). These two circumstances (i.e., an older age profile and higher school dropout rate) imply that the undocumented are a smaller share of Illinois' school population. Therefore the undocumented in this state use relatively little in the way of state and local services.

Following further the lessons from scenario A, the gap in per capita service usage between the undocumented and the rest of the population is roughly $200 in California ($1,124 compared to $906), $100 in Texas, and negative in Illinois. The revenue gap is much larger in all three states. In the three states considered as a whole, the undocumented pay about $500 per person in state and local taxes, the rest of the population pays far more: in California about $1,400 per person; in Texas and Illinois about $1,000 per person. When costs are subtracted from taxes paid, to yield a net cost or burden per capita, the undocumented in California run a per capita deficit of $588, while the rest of California pays $518 more than it uses in services. Of course, these figures must be examined with caution because, as we noted above, this is not a complete fiscal accounting, and many kinds of services and revenues are left out. Still, the calculations show that the undocumented population most likely poses a fiscal burden on each of the states, because of the low rate of state and local taxes that undocumented migrants pay. Among the three kinds of taxes analyzed (sales tax, property tax, and state income tax), the migrants pay less of each type on a per capita basis because they have low incomes.

The fiscal gap between the undocumented and the rest of the population is much higher in California than in Texas or Illinois for two reasons: (1) the per capita revenue gap is highest in California, and (2) the undocumented population is far larger in California than in the other states. California has a sizable state income tax, to which the undocumented contribute only about $30 per person, while other Californians contribute more than $500 per person. Income taxes are very progressive at low income levels because most working poor people tend to have little taxable income. The undocumented may also be able to avoid compliance with some or all of their income tax responsibilities. Texas, on the other hand, has no income tax, but only sales tax and property tax. These taxes are much less progressive. For example, in the case of the property tax, renters pay it as part of their rent. As a result, the per capita revenue gap between the undocumented and the rest of the population is much less in Texas than in California. In Texas the undocumented pay $579 per capita in taxes compared to $968 per capita for the rest of the population. However, in California the undocumented pay $536 while everyone else pays $1,424 per person.

Focusing on the total net fiscal burden of the undocumented in each state, California bears the heaviest burden ($829 million), while the burden in Texas is much smaller ($194 million), and the burden in Illinois is almost trivial ($17 million) relative to the state budgets. These net figures are much smaller than the states' estimates used in claims against the federal government because the states' costs (but not revenues) are based on somewhat inflated figures for the undocumented population (see Clark et al, 1994; GAO, 1994).

There is no disagreement that California bears the brunt of new immigration, including undocumented migration. Therefore, it is logical that California experiences the heaviest fiscal burden due simply to the sheer number of immigrants it receives, as documented above. Table 7 shows that not only is California faced with by far the largest number of undocumented migrants, but also that the fiscal impact of this migrant stream is magnified by a relatively large per capita fiscal gap between the undocumented and the rest of the population. This gap results from the higher rate and more progressive nature of the tax system in California, which leaves the undocumented paying a smaller share of the total state and local tax burden.

Among the costs that can be *directly* attributable to illegal migrants, by far the largest is the cost of primary and secondary education. Cognizant of difficulties in accounting for the citizen children of illegal immigrants, in scenario B we recalculated the fiscal impacts by categorizing these children differently. In scenario A, only children who are themselves foreign-born and undocumented are counted among the undocumented school-age population. In scenario B, we augment this population by including the citizen children of the undocumented migrants on the grounds that their parents' unauthorized presence incurred their schooling costs. We assumed that this restriction would increase the 'undocumented' school age population by 25% . These results are presented in Table 7, scenario B. Although the undocumented population of primary and secondary students has increased 25% over that reported in scenario A, the total undocumented population has increased only about 5% (from 1.41 million to 1.48 million in California). Consequently, the total cost of services to the undocumented in California arose by 18%, from $1.58 to $1.87 billion, and the net fiscal burden increased substantially, from $829 million to $1.08 billion.

The final scenario reported in Table 7, scenario C, uses the states' own estimates of the undocumented population, which is considerably higher than the Census Bureau's high end estimate for the undocumented population in 1992. This scenario increases the undocumented population in California by 673,000 over the 1.4 million in scenario A, a gain of almost 50% (note that the states' total populations also change in this scenario, to accommodate the previously uncounted persons). The total costs in scenario C are different from the total

costs in the states' claims because we use per capita costs and revenues based on Clark et al. (1994), which differ from those provided by the states in some particulars. Using the states' inflated undocumented population estimates combined with estimates of various costs established by Clark et al., scenario C shows that the undocumented population in the three states (CA, IL, and TX) consume, respectively, $2.17 billion, $173 million, and $611 million in state and local services. The states' own estimates of these particular costs, using these population figures and their own methodologies yielded costs of $2.8 billion (California), $151 million (Illinois), and $362 million (Texas).

It is noteworthy that although scenario C increases the undocumented population much more drastically than scenario B, scenarios B and C yielded similar aggregate fiscal burdens for undocumented immigration. For California, the undocumented are more costly to the state and local treasuries under scenario B ($1.08 billion total cost) than in scenario C ($1.055 billion). Both scenarios B and C naturally increase the fiscal burden over scenario A ($829 million). For Texas, scenario C is the most costly. In scenario C the total costs and total taxes paid by the undocumented both increase sharply. In scenario B, which increases only the crucial school-age population (due to reclassification), the total costs increase substantially but the total taxes paid by the undocumented population increase only slightly.

Although scenario C uses a figure for the undocumented population that is 48% higher than scenario A (2.083 million as compared to 1.41 million), for California the total net fiscal burden of the undocumented is estimated to increase only by 27% (from $829 million to $1.055 billion). This is because some of the costs are assumed to be fixed. Even if the size of California's undocumented population is unknown, officials do know exactly how many of California's state prisoners are foreign-born and among these, how many are undocumented. Changing the estimates of the undocumented migrant population does not affect how many undocumented migrants were actually incarcerated in California in 1992 or 1993. Therefore, future simulations of the possible fiscal impacts of migration on prison costs would yield predictable and consistent variation in these parameters, such that a 50% increase in the migrant flow would yield a 50% increase in net total fiscal costs attributable to prison expenditures.

The previous analysis focused on undocumented immigration, which is important because it underscores ineligibility for tax-supported benefits and services. This is, after all, the major source of tension about the economic costs of immigration. However, the National Academy of Sciences study considered fiscal impacts for the state of California (as well as New Jersey) based on the total foreign-born population in that state. This analysis can not differentiate between undocumented and documented immigrants, yet it furnishes a different perspective of fiscal impacts by focusing on households rather than individuals as the unit of analysis, and

by considering the entire foreign-born population (rather than mainly undocumented migrants) in the analysis. This is important because most immigrants residing in California were admitted legally. This study concluded that the net fiscal burden incurred by California households headed by immigrants was $1,178 per household headed by a native-born individual. The analysis indicated that households headed by immigrants made small positive contributions to the federal government (on the order of $2 to $4 per year reduction of federal taxes for resident households), but this benefit is tiny by comparison to the costs incurred by the state. The study also concluded that the net burden is greatest for households of immigrants from Latin America, among which Mexicans are the dominant group.

This analysis highlights several problems identified above. First, the current year estimates understate future benefits and overstate current costs. Second, use of households as analytic units defined by the nativity status of the head overstated the education costs by attributing the education costs of native-born children of immigrant heads in the expenditures of immigrants.

National Level Fiscal Impacts

In this brief section we have focused on state-level fiscal impacts for three reasons: geographical specificity allows us to focus more narrowly on migration from Mexico; fiscal impacts are strongest in migrant receiving states like California; and as a result there is more scholarly consensus about the sign, if not the magnitude, of these local fiscal impacts. National level fiscal impact studies attempt to answer a broader question: whether foreign-born migrant's net contribution to the coffers of the United States are positive or negative. A wide range of views have been proposed.

Simon (1981, 1989), using data from the 1976 Survey of Income and Education, takes the most positive view. He argues that immigrants (who are a much younger population than natives) contribute to the Social Security program without being eligible (at least not in the short term) for benefits. Essentially this implies that newcomers subsidize natives through their Social Security contributions. At the other end of the spectrum, Huddle (1993, 1995) has presented the most negative picture of immigrant's national fiscal impact. Huddle's first work did not take the Social Security program into account, and his later work applied the current value of a lifetime of potential Social Security benefits to each immigrant, while counting the Social Security tax contribution only of the current year. Fix and Passel (1994) and Passel and Clark (1994) have severely criticized Huddle's methodology, and the debate between these authors is described in detail in GAO (1995). On balance, this discussion has not been productive in producing a balanced assessment of fiscal impacts.

Attempting a response to the limitations of static assessments of fiscal impacts of immigration, the National Academy study (1997) derived a set of projections about long-term fiscal impacts using varying assumptions about future expenditures and revenues, immigrant characteristics, including behavioral differences in fertility, labor force activity and program participation. Adhering to the recommendation of an earlier workshop about fiscal impacts (NAS, 1996), the panel generated a range of estimates based on alternative assumptions about the characteristics of immigrants, their behavior, and taxation regimes. Not surprisingly, the study concluded that differences between native- and foreign-born populations in expenditure profiles vary appreciably by program and depending on the assumed characteristics of the immigrant population.

The bottom line conclusion is noteworthy, however. Combining the costs of benefits from all programs, there is little difference between immigrants and natives over their respective lifetimes. *Immigrants are more costly than natives during childhood owing to the costs of bilingual education, while they are less expensive than natives in older ages. Over a lifetime, these differences balance out. Therefore, the long-term net fiscal impact of any given group depends crucially on age at arrival.* The greatest benefits for natives result from immigrants who arrive between ages 10 to 25, while the largest costs derive from immigrants who are over age 60 at the time of arrival. Moreover, the fiscal estimates of the impact of immigration are affected more by future income and earnings differences between immigrant and native-born households than by nativity differences in program participation. In turn, these depend crucially on the educational attainment of immigrants at arrival.

Discussion

While the issue of national level fiscal impacts is an important one, we have concentrated on state and local impacts here for a number of reasons. The literature on state and local level impacts has recently become more developed in response to the demands of local politics, especially in California, where the economic impact of immigrants is the source of considerable political tension. Even if the fiscal burden of immigrants on the state and local level were offset by immigrant contributions to the national coffers (especially through Social Security taxes), this would not diminish the reality and importance of the local costs. Since the political debate over immigration originates in the immigrant receiving states, the focus on local effects is important in its own right, in addition to its part in the larger national economic picture.

One of the most important lessons from the current state of research on the fiscal impact of immigration, and the impacts of immigration more generally, is

that very little is known for certain. Of all the economic costs attributed to immigration, the current year fiscal impacts should be the most straightforward to calculate because a current year analysis of fiscal impacts need not consider (difficult to estimate) indirect economic effects, secondary migration of natives, the effect of immigrants on natives' wages, or life cycle changes in earnings. And yet, as our simple exercise above has demonstrated, different (plausible) assumptions lead to very different results in even the most narrowly defined fiscal impact analysis.

We based our own secondary analysis on the empirical results of Clark et al. (1994) because their study is among the most meticulous methodologically, and also because they adhere to limited and cautious claims warranted by what is actually known. Considering that careful estimates of the undocumented immigrant population vary by as much as 15 percent or more, caution and humility are necessary in drawing conclusions about the fiscal impacts associated with immigration generally, and particular segments of the immigrant population specifically.

Currently a good deal is known about immigrants' usage of welfare and other means-tested income transfers (as we show below) and it is also possible to estimate reasonably the number of undocumented immigrant children in the schools (which depend on how we define the statuses of families and children). However, we know very little about how immigration influences the cost of providing other services like highways, parks, clean air, libraries, and national defense. Studies that claim to provide a full fiscal accounting of all services and all government revenues, even at the state level, make broad assumptions about the consumption of and marginal cost of providing these various public goods. The recent National Academy of Sciences report on immigration presents a "complete" fiscal impact study for California, based on the work of Clune (1996), which draws mainly on the Current Population Survey. In the absence of a detailed survey of the marginal cost of public goods specific to each state and locality, and the consumption of these goods by immigrants who, after all, have a different demographic, geographic, and economic profile from natives, even this allegedly "complete" fiscal impact study must be viewed with caution.

Our final caveat relates to the static versus temporal portrayal of fiscal impacts. Our discussion, and most empirical studies, have concerned themselves with static, single year time frames, whereas the fiscal impact of immigrants that ought to concern us is the impact over the life span of immigrants. In the static model, education is a cost. Yet, a large body of empirical evidence shows that education is fundamentally an investment in future skills and earnings. Therefore, estimates of fiscal impacts should reasonably expect that the current cost of education will be recovered in the future in the form of greater productivity.

The National Academy of Sciences has properly emphasized the future in portraying fiscal impacts over the life course of immigrants (Smith and Edmonston,

1997). However, its main limitation is that long-term fiscal impacts are not based on longitudinal data that accurately portrays immigrants investment behavior (education) and economic activity over the life course. The National Academy of Sciences based their analysis of life course fiscal impacts on two years of Current Population Survey data. Yet, a substantial body of empirical evidence has taught the social science community that cross-sectional data cannot distinguish between longitudinal and cohort effects. New and innovative work, as the National Academy has done, is always to be applauded; we simply advise that the current state of the knowledge in the area of fiscal impacts mandates caution and care when interpreting the results.

Conclusions about Fiscal Impacts

Despite the numerous caveats surrounding available estimates of fiscal impacts, several generalizations follow from the evidence presented above. The broadest generalization is that fiscal impacts of Mexican immigration differ by legal status; by state of residence; by program; and by age groups. Second, conclusions about fiscal impacts differ depending on whether a static or longitudinal time frame is used to assess impacts; whether individuals or households are used as analytic units in calculating revenues and expenditures; and the assumptions about the size of the undocumented population. Third, because California receives the largest share of Mexican—both legal and undocumented—and because of its tax structure, it also incurs the largest fiscal impacts. Finally, the net fiscal benefits associated with immigration generally accrue to the federal government (via federal taxes) while the net costs generally accrue to local entities, i.e., states and counties (Smith and Edmonston, 1997).

That conclusions about costs and benefits differ by program and between levels of government is unsurprising, and questions the wisdom of seeking a single answer about fiscal impacts at a single point in time. Rather, fiscal impacts should be calculated over the lifetimes of immigrants so that, depending on age at arrival, periods of dependency can be balanced against periods of economic productivity. Thus, according to the National Academy of Sciences that "combining the costs and benefits from all programs, *there is little difference between immigrants and natives over their respective lifetimes*." Short-term impacts of Mexican immigrants depend crucially on age at arrival and schooling levels, which determine labor market options. Longer term fiscal impacts depend on income and earnings differences relative to native workers, fertility (which influences the educational investments required by children of immigrants), and state of residence (which determines the progressiveness of the tax structure).

Socio-political Impacts

As noted in the introduction to this chapter, social impacts of the Mexican foreign-born population are especially difficult to appraise because of the myriad ways migration changes the host society; because migrants themselves change in the process of adapting to the host society; because social impacts are highly contingent on more general demographic and economic trends; and because many social dimensions, especially those relegated to the cultural realm, are not easily quantified. Social impacts also depend crucially on the resources Mexican migrants bring with them as well as those they acquire and transmit to subsequent generations; on patterns of inter-marriage, particularly with non-Hispanics; and on naturalization patterns and political participation. Finally, social impacts also are shaped by public perceptions about job competition, views about undocumented migration, and attitudes about crime and its relation to rising immigration trends. In this section we consider each of these themes and provide tentative conclusions about how Mexican migration impacts these social spheres.

Residential Segregation and Neighborhood Transformation

Residential patterns are important for appreciating social impacts because social and economic resources are unequally distributed over space; hence, residential location determines access to education, employment, and housing opportunities as well as levels of safety. Residential segregation not only undergirds unequal access to social and economic resources and opportunities, but also restricts inter-group contact, which is important for promoting understanding and reducing ethnic tensions.

Residential segregation may be voluntary, as frequently occurs when new migrants settle in neighborhoods populated by compatriots, or it may be imposed, as when restrictive covenants prevent particular groups from accessing the housing market (Massey and Denton, 1993; Clark, 1996). Currently as well as historically, most recent migrants to the United States (including Mexicans) settle in ethnic neighborhoods, which serve as stepping stones for economic and social adaptation of the first generation (Smith and Edmonston, 1997). Over time, the residential trend is toward dispersion, as the second generation becomes more socially and residentially integrated (Bean and Tienda, 1987; Clark, 1996; Smith and Edmonston, 1997).

It is unclear, however, whether residential mobility experienced by Mexican migrants who arrived prior to 1970 will be repeated by the second generation offspring of recent migrants, notably those whose parents have confronted shrinking

opportunities for earning a living and diminished educational institutions in decaying urban neighborhoods. This is because, in contrast to the residential succession patterns observed during the 1960s, most of the neighborhoods that had gained Hispanic residents before 1970 subsequently lost Anglo residents throughout the following decade. This trend was accelerated during the 1980s, when immigration increased Mexican density of traditional enclaves (Ortiz, 1996). In Los Angeles county, host to the largest share of recent migrants from Mexico, the 1980s witnessed increased segregation of Mexicans from whites compared to the 1970s, but paradoxically, inter-group contact (as measured by the exposure index, P*), declined (Ortiz, 1996).

Even if Mexican migrants become residentially dispersed over the long term, the short-term patterns of residential segregation are important nonetheless because they heighten visibility of recent arrivals and shape perceptions about them. In the short to medium term the temporal and residential concentration of Mexican migrants is a driving force behind residential succession, namely the process of neighborhood turnover that occurs as Mexicans enter an area and replace (or displace) its original inhabitants. In turn, residential succession fueled by Mexican migration during the 1970s and 1980s has restricted inter-group contact between Mexicans and Anglos in several major cities, including Los Angeles and Chicago (Bean and Tienda, 1987: Chapter 5; Clark, 1996; Ortiz, 1996).

Changing residential patterns are important because they reflect the pace of social and economic integration and lay the spatial foundations for inter-group relations, including ethnic tensions and conflict. Bobo and Zubrisky (1996) have explored racial segregation and ethnic interaction issues via surveys in Los Angeles, home to the largest Mexican population residing in the United States. They observe that whites are more opposed to housing integration with blacks than with Hispanics (in Los Angeles, Hispanics consist almost entirely of Mexican Americans and migrants from Mexico). Other groups, such as Asians, seem to share the same preference for Mexicans over blacks as neighbors. It appears that migrants occupy some kind of intermediate social position between native whites (whom all groups, including blacks, rate as the most desirable neighbors), and native blacks (who are rated by all groups as the least desirable neighbors). However, Mexican migrants do not occupy an intermediate social position because they are middle class or reside in neighborhoods with whites. Rather, as Clark (1996) has shown, Mexicans in Los Angeles are more likely to be residentially integrated with black and Asian neighbors now than in the past. In other words, much of the residential integration that has occurred in recent years is with other minorities, not with whites, but this depends on social class.

Although residential segregation often limits access of migrants to socioeconomic resources and opportunities, Mexican migrants also appear to forestall

neighborhood decay. A recent study of Chicago reveals that Mexican migration either contributes to community revitalization or prevents decaying inner city neighborhoods from becoming underclass neighborhoods, characterized by persistent poverty, chronic and pervasive joblessness, and generalized social disorganization. Morenoff and Tienda (1997) use a cluster analysis to identify four distinct kinds of neighborhoods (census tracts) in Chicago from the 1970, 1980 and 1990 censuses. The different kinds of neighborhoods (underclass, working class, stable middle class and "yuppie") are defined using only socioeconomic variables, not race or ethnicity. Morenoff and Tienda show that from 1970 to 1990 Chicago experienced a tremendous polarization in neighborhoods inhabited by U.S. born residents. By 1990, most of the neighborhoods that in 1970 were working class and stable middle class neighborhoods had either gentrified, or were absorbed into Chicago's black ghettos, abandoned by all but the poorest residents. The only parts of Chicago in which working class neighborhoods have grown or even been maintained are those areas settled by migrants from abroad. During this period Mexicans and Europeans (mainly Poles) were the predominant migrant groups settling in Chicago.

Their results suggest that residential patterns of Mexican migrants may serve as a buffer between the so-called "underclass" and middle class urban neighborhoods. Thus, the impact of Mexican migration on urban communities and the urban stratification system more generally depends both on changing economic opportunities and the changing race and ethnic landscape (Waldinger and Bozorgmehr, 1996). Although Chicago's experience may be a unique in many ways (because it is the only large city where shares of Puerto Ricans and Mexicans approximate the national population and because the city population was over 60 percent minority in 1990), it is worthwhile to consider whether the residential patterns of Mexican migrants buffer the neighborhood polarization process in other cities, especially Los Angeles and Miami, whose population composition has been transformed by immigration since 1960 (Waldinger and Bozorgmehr, 1996; Portes and Stepick, 1993). Political theory has always recognized the importance of a sizable intermediate and middle classes, and no political system is more inherently unstable than a bifurcated system. At least in Chicago's socio-political system, Mexican migrants appear to be a stabilizing force in the process of urban transformation.

Immigrant Adaptation and Social Mobility

The reality or myth of the hardworking immigrant, striving and saving to get ahead is a potent image that helps to reinforce the American creed of meritocracy. Despite lower levels of education and lower earnings, some studies show that Mexican Americans and Mexican migrants fare better economically and socially than native blacks of comparable or higher education (Trejo, 1997a;

Tienda and Stier, 1996). The tabulations reported at the beginning of this section consistently show that male Mexican migrants were disadvantaged relative to native blacks in terms of educational attainment and language skills, yet in most states had higher rates of labor force participation and usually lower unemployment rates. That the most economically and socially disadvantaged groups are not immigrants, but rather citizens of African American, Native American and Puerto Rican origin suggests that Mexican migrants have a reasonable chance of adapting to U.S. labor market and society, economic opportunities permitting, as have several prior generations.

On this crucial issue, there is some disagreement among scholars, depending somewhat, but not exclusively, on perspective. A recent study of Los Angeles painted a bleak picture of Mexican migrants' economic integration between 1960 and 1990. Using a synthetic cohort analysis, Ortiz (1996) showed real increases in earnings of Mexican migrant men between 1969 and 1989, but these were smaller than the real earnings growth of white men. As a result, the earnings gap between native born white men and Mexican migrants widened over the past 30 years. Women followed a similar trajectory, except that their earnings were even lower than those of men. Unfortunately, Ortiz does not carefully model earnings, thus her pessimistic conclusions need to be tempered because she does not consider how much the apparent slowdown in economic assimilation of Mexican migrants in Los Angeles results from their low levels of human capital relative to changes in demand for unskilled labor.[33]

Trejo's (1997a) analysis of wages of Mexican-origin men is not only more revealing about the process of economic assimilation, but also quite optimistic about long-term integration prospects. Based on an analysis of 1979 and 1989 Current Population Surveys, Trejo compares the wage growth of first, second, and third generation Mexican-origin men with that of native whites and blacks. Trejo's (1997a) main finding is that Mexican-origin men earn low wages primarily because of their lower stocks of human capital, notably education and low proficiency in English, not because they receive lower returns for their skills. Trejo also suggests that wage penalties for lack of fluency in English may have increased during the 1980s, when returns to skills rose appreciably, and this bodes ill for the pace of integration of Mexican migrants in the future.

So, too, does the reality of low levels of education. Although a generational perspective shows improvement both in educational attainment and in economic assimilation of Mexican origin men, the educational attainment of Mexicans (both native and foreign-born alike) is the lowest of any ethnoracial group (see Mare, 1995; Chiswick and Sullivan, 1995). Thus, owing to changes in the educational composition of recent migrants from Mexico, the average wages of Mexican origin men are dragged down by the presence of large numbers of immigrants with very

low levels of education. In a subsequent paper, Trejo (1997b) compares nativity differentials in the earnings of Mexican origin men and finds that the sizable earnings advantage of native born men over their migrant counterparts arises not just from intergenerational improvements in years of schooling and English proficiency, but also from increased returns to human capital for Mexican origin workers who were born and educated in the United States. However, he also observes that intergenerational changes in the wage structure take longer to play out for Mexicans than for other white migrant workers.

According to Trejo, the returns to experience are similar for U.S.-born workers regardless of origin, but Mexican returns to education rise for each successive generation and do not approach the schooling returns of U.S.-born whites until the third generation. These results show promise of economic integration of Mexican migrants, which, in turn, have direct and indirect implications for various types of economic impacts (Smith and Edmonston, 1997). However, the pace of convergence with native whites implies persisting economic disadvantages of Mexican origin men and women. More importantly, these disadvantages are likely to persist and possibly increase as the volume of unskilled migration from Mexico continues.

Similar conclusions were reached by Tienda and Singer (1995) based on their analysis of the economic integration prospects of the legalized population. They showed that the average education level of Mexicans, who made up over 70 percent of the legalized population, actually increased over time, from an average of less than 6 years for the pre-1975 arrivals to 9 years for those who arrived during the 1980s. They also showed positive growth in real wages for cohorts that arrived after 1975 coupled with real wage declines for those who arrived before 1975. In other words, earlier arrivals experienced wage deterioration which paralleled that experienced by unskilled native workers. Finally, in response to the question of whether undocumented immigrants can be economically assimilated, Tienda and Singer demonstrated positive real wage returns to U.S. experience in an undocumented status for all regional origin groups.

The suggestion that returns to English proficiency may be rising over time (Trejo, 1997a) is noteworthy from the standpoint of social impacts because Mexicans have higher rates of Spanish language retention than other recent immigrants (Lopez, 1996; Ortiz, 1996). Lopez (1996) emphasizes that exposure to other immigrants, not generational status, is the most powerful predictor of language maintenance. Moreover, persons born in Mexico as well as native-born persons of Mexican ancestry have low rates of internal migration, which is both a consequence and a cause of Spanish language maintenance. In this regard, the forces for retaining Spanish in public and private settings is particularly high for Mexicans, not only because of the sheer volume and residential concentration of recent flows, but also because Mexican Americans are less likely to migrate internally and more likely to

reside in multi-generational households that include one or more foreign-born persons (Lopez, 1996). These living arrangements slow the pace of language shifts among Mexican American households. Ortiz (1996) shows that in Los Angeles, the proportion of younger Chicanos who reported speaking Spanish at home rose between 1980 and 1990. She argues that this change reflects an increase in the share of young people with foreign-born parents rather than a change in the pace of language shift, but this is not obvious from the evidence presented. In any event, the role of Mexican migration in Spanish language maintenance is undeniable.

The tendency for Mexican migrants to reside in densely settled ethnic neighborhoods promotes maintenance of Spanish language use in public spheres further slows the shift toward exclusive language use. Public use of Spanish is more socially significant for ethnic relations than is private usage (Lopez, 1996). In cities that have been highly impacted by recent immigration from Mexico and other parts of Central and South America, Spanish usage is common even in non-Latino neighborhoods. This is because Spanish-speaking in public places is associated with the manual industrial and service occupations in which Mexican migrants are disproportionately represented, especially southern California, Texas and Chicago. Thus, Spanish usage has come to symbolize membership in the lower rungs of the working class (Lopez, 1996).

Naturalization and Political Participation

There are many political dimensions of Mexican migration and Mexican American life in the United States. Identification and measurement of political impacts of Mexican migration are highly complex and often indirect, which compounds the difficulty of measurement and assessment. Political life in the United States, as elsewhere, includes the realms of routine electoral politics where candidates seek votes, symbolic politics where images of migrants may be put to a variety of uses, and legislative politics where rights and privileges of different groups may be gained or lost.

If the migrants cannot vote, no direct effects seem forthcoming on routine electoral politics in the United States, but several links between migration and electoral politics exist, some direct and others indirect. Just as the econometric literature has tended to show that the labor market impacts of migration, when they are measurable, are mainly felt in communities where earlier migrants settled, so, too, the various political impacts of Mexican migration are felt primarily in Mexican American communities.

The foreign born affect electoral politics directly through census enumerations and decennial redistricting. U.S. congressional districts and all state legislative districts are apportioned on the basis of persons, rather than on the basis of citizens or

adult citizens because of the wording of article 1, section 2 of the U.S. Constitution (the U.S. is quite unusual in this regard). In the aftermath of the Voting Rights Act of 1965, which was extended in 1975 to include protections for Mexican Americans, some legislative districts have been designed to be minority dominated to insure greater minority representation in the various legislative bodies.

Because these districts are designed to contain a specified number of people, rather than a certain number of adult citizens, Mexican-American districts have many fewer potential (and actual) voters than other districts. Table 8 shows that in the 1992 U.S. elections, Mexican Americans cast only about 16 votes per hundred *persons*, while non-Hispanic Whites cast about 50 votes per hundred persons. The low number of Mexican-American votes derives from several factors—younger population, lower naturalization rates coupled with relatively low registration and voting rates. The most important difference is the low adult citizenship rate, 54 percent as compared with 95 percent for non-Hispanic Whites and 92 percent for non-Hispanic blacks. Even though they cannot vote, Mexican migrants ought to be considered a political asset for the adult U.S. citizens in established Mexican-American communities because the political clout of the established communities partly depends on the creation of safe districts, and the legislative districts depend on a sizable number of migrants.

The political demography of immigration also implies costs for established Mexican-American communities. Skerry (1995) and others have argued that the presence of large numbers of Mexican migrants, most of whom are quite disinterested in American electoral politics, dilutes the natural bonds between the elected officials and the adult citizens whom they most directly represent. Whether the presence of large numbers of migrants makes it harder for elected officials to reach out to their natural constituents (the adult citizens), and whether or not the representatives from Mexican-American districts have limited clout because of the paucity of voters in their districts, there is no doubt that Mexican-American communities are far less politically powerful than they potentially could be. The low registration rates and voting rates by Mexican-American adult citizens are substantial evidence, though not the only evidence, for weaknesses in political organization.

Mexican immigrants have the lowest naturalization rates of any foreign national origin group of substantial size in the U.S. Low naturalization rates can be seen as a proxy for the very limited attachment of Mexican immigrants to American politics, although some other factors (such as the potential loss of property in Mexico) have historically played a role in keeping the naturalization rates of Mexican immigrants down. On the other hand, the U.S.-born children of Mexican migrants are automatically U.S. citizens and these subsequent generations will be primarily attached to the U.S. political system, and in principle will augment the political power of established Mexican-American communities. But

Table 8
Demography of Political Participation, 1992

	Mexican Americans	Non-Hispanic Blacks	Non-Hispanic Whites	Other Non-Hispanics	Cubans	Puerto Ricans	Other Hispanic
Persons	15,267,776	32,077,899	192,958,425	8,780,088	1,122,381	2,640,295	4,715,788

the naturalization profile of Mexican immigrants may change because immigrants granted amnesty have recognized that citizenship broadens their possible sponsorship of other family relatives and because citizenship safeguards eligibility for social welfare benefits.[34]

How Mexican migrants influence the political life of Mexican Americans, and by extension the American political system as a whole, largely depends on the political solidarity, or commonality of purpose, between the migrants and the co-ethnic U.S. natives. A comparison between the Cuban-American and the Mexican-American communities is instructive. Refugees from Castro's Cuba have generally found a substantial amount of political solidarity in the already established Cuban-American community (mainly in Florida) due to their shared and often strident opposition to the Castro regime (Portes and Stepick, 1993). Cuban immigrants have much higher naturalization rates than Mexican immigrants, and as Table 8 shows, Cuban-American citizens have registration and voting rates that far surpass those of Mexican Americans and sometimes exceed those of native whites. (Income and class, of course, play an important role along with sociopolitical factors in determining political participation). The political solidarity between Cuban immigrants and Cuban Americans has helped the Cuban-American community attain a political strength far beyond their numbers (Portes and Stepick, 1993).

Mexican Americans, on the other hand, seem to be more ambivalent about newer migrants from Mexico. Various surveys conducted and reported by de la Garza and his colleagues (de la Garza et al, 1992) have demonstrated a considerable lack of support among Mexican Americans for the rights of new immigrants. Various election day polls (Ayres, 1994) from 1994 showed that as many as 30 percent of California's mostly Mexican-Hispanic voters supported Proposition 187, arguably one of the most egregious pieces of anti-immigrant legislation in the post-Civil Rights era.

It is noteworthy that the Mexican-American community has substantially increased its power in electoral politics since 1970, and therefore the political impacts of Mexican migration, mediated through a complex relationship with established Mexican-American communities, may have *indirect* effects on elections and legislation at the local and national level. In presidential politics, the concentration of Mexican Americans in three important states (California, Texas, and Illinois) could potentially give Mexican-American voters significant leverage. However, such leverage, if it is forthcoming, would depend on the state in question being very closely contested, and on high voter turn out and block voting among Mexican American voters. While Mexican-American voters have generally favored Democratic over Republican candidates in presidential elections in proportions almost high enough to qualify as "block voting," the low turnout of Mexican

Americans, and the lower fund raising potential of the Mexican-American community compared to other constituencies means that national candidates are likely to continue to view the Mexican-American electorate as a marginal, rather than a central player.[35]

The designation of Mexican Americans as a "minority" group is a designation with social, demographic, and political implications. In many ways, Mexican Americans first became an official minority in 1975, when Mexican-American groups led by MALDEF (Mexican American Legal Defense and Educational Fund) made a successful effort to get the Congress to extend the protection of the Voting Rights Act (widely viewed as the most successful civil rights legislation in American history) to Mexican Americans. In general, Mexican-American political organizations tend to identify themselves with a coalition of minority interests, but Mexican Americans themselves are deeply ambivalent about their minority status (Skerry, 1993). While Mexican-American politicians in the U.S. Congress tend to find much common ground with black congressional leaders (both groups are predominantly Democratic, mostly urban, and largely progressive on fiscal issues), on the local level, such black- Mexican coalitions have proven much harder to create or sustain.

Crime

There is a general perception that high levels of migration and high crime rates are causally associated. Between 1960 and 1990, the annual migration rate rose from 1.7 to 3.0, while the homicide rate increased from 4.8 to 8.3 (Hagan and Palloni, 1996). Unfortunately, relatively little research addresses the association between changing crime and migration rates, and even less information focuses on the involvement of particular groups of migrants in criminal activity.

According to the 1991 Survey of State Prisons, Mexicans account for nearly half of the foreign-born population in state prisons. However, this does not establish that Mexicans are more prone to crimes than other migrants to the United States or U.S. natives. Rather, the over-representation of Mexicans among the foreign-born prison population reflects differences in treatment through the criminal justice system. Specifically, migrants along the border are more likely to be arrested, detained prior to trial, and consequently, to be convicted and imprisoned. Undocumented migrants also are less likely to be released from jail prior to trial. Because Mexicans are disproportionately represented among migrants detained along the border and among undocumented migrants, they are incarcerated at rates from 2 to 4 times those of citizens (Hagan and Palloni, 1996). However, gross differences in the incarceration rates of Mexican and U.S. citizens disappear once differences in age structure (because Mexicans are younger and petty crime rates

are higher among the young) and especially the differences in treatment in the criminal justice system of Mexicans and Anglos are taken into account. Thus, Hagan and Palloni (1996) conclude that for Mexicans the temporal association between migration and crime is coincidental rather than causal.

That property crime rates (but not violent crime rates) along U.S.-Mexico border cities are relatively high has fueled perceptions that migrants, and Mexicans in particular, are somehow responsible. There is some evidence that high crime rates along the U.S.-Mexico border are related to the level of undocumented migration, but not legal immigration (Hagan and Palloni, 1996; Smith and Edmonston, 1997). However, crime rates have fallen in recent years even though migration from Mexico, including unauthorized migration, has remained high. This situation affords an opportunity to set the record straight about the lack of causal connection between Mexican migration and crime rates along the U.S.-Mexico border. That is, crime rates along the border are below those of comparable non-border cities (Smith and Edmonston, 1997; Hagan and Palloni, 1996). Nevertheless, perceptions that crime along the border is due largely, if not exclusively to Mexican immigration may be more influential than facts in shaping policy responses to immigration. Therefore, our final section discusses recent evidence about attitudes toward and perceptions of Mexican migration to the United States.

Attitudes and Perceptions

Much of the current debate about immigration, and Mexican migration in particular, is fueled by distorted perceptions about the costs and benefits of migration rather than facts. This is significant because perceptions are crucial in shaping reactions to immigration. Two general changes in attitudes toward immigrants are germane for understanding the rising tide of anti-immigrant sentiment, and anti-Mexican sentiment in particular (Espenshade and Belanger, 1997). First, several recent polls suggest that anti-immigrant sentiment is on the rise. Nearly two of every three people surveyed in 1995 reported that U.S. immigration should be reduced. A similar level of disapproval arose in the early 1980s, when unemployment reached 10 percent. However, when given a choice, the majority of the U.S. population preferred immigrants from Europe and Asia over those from Latin America. And, among Latin American immigrants, those from Mexico were least preferred.

Second, the general public exaggerates the pervasiveness of undocumented migration as a share of total immigration from Mexico (Espenshade and Belanger, 1997). Several polls conducted during the early 1990s revealed that two of every three respondents surveyed believed that the majority of migrants were undocumented. In fact, Mexico-U.S. relations are so confused in the public mind

that nearly one in three respondents to a public poll indicated that illegal immigration was the greatest worry about the future of Mexico. The negative views about immigration, and Mexican migration in particular, reflect perceived job competition of undocumented migrants with domestic workers. Finally, when queried whether undocumented immigrants should be denied access to health and education, more than half of respondents answered affirmatively. The rising tide of anti-immigrant sentiment has been matched with legislation that attempts to deny immigrants access to collective consumption services and benefits of all kinds, except in the event of dire emergency. Restrictive policies of recent years, especially the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (P.L. 104-193) appear to have deep foundations in perceptions and more shallow foundations in fact.

Conclusions about Socio-political Impacts

Our general overview of social impacts points to several general conclusions, some more tentative than others. Although Mexican migrants tend to concentrate residentially, especially upon arrival, the available evidence points to residential integration over time. The 1980s witnessed an increase in residential concentration of Mexican migrants, but partly this reflects the intensity of the flow and the disproportionate share destined for a few labor markets in the Southwest. Nevertheless, residential concentration patterns imply concentrated impacts and possibly a slower pace of socio-cultural assimilation. This is evident in the high rates of Spanish language retention, which in turn, has implications for educational attainment and labor market integration of subsequent generations.

Social integration depends crucially on economic assimilation. Although there remains some controversy about whether migrants from Mexico can be integrated economically, recent econometric evidence suggests that second and third generation Mexican American men earn higher wages than their foreign-born counterparts of comparable human capital. In other words, the large wage gap between Mexican and non-Hispanic white men, and between native and foreign-born Mexican origin men, is largely attributable to group differences in levels of educational attainment and English proficiency. This is not a trivial issue, however, because Mexican migrants possess significantly lower human capital stocks than U.S. natives (including blacks) and because the demand for unskilled workers has fallen, thereby virtually ensuring low wages for those who do manage to get a foothold in the labor market.

Political impacts of Mexican immigration hinge on rates of naturalization and settlement patterns. The concentrated presence of Mexican immigrants increases the size of communities and the likelihood of indigenous representatives.

However, the low rates of naturalization coupled with the low voting rates weaken the potential impact of Mexican immigration on the political system, at least in the short run. Owing to poor data about immigrants and the criminal justice system, it is difficult to draw conclusions about the impact of Mexican migration on crime. Nevertheless, Mexicans do not appear to be more prone to crime than U.S. natives, and the major trends in crime along the Mexico-U.S. border appear not to be driven by migration. Finally, rising opposition to Mexican immigration appears to be based on mis-perceptions about the prevalence of undocumented migration in the total flow of Mexican migrants, and perceptions that Mexicans take jobs away from domestic workers. Whether right or wrong, these perceptions are quite profound in their consequences.

Conclusions and Recommendations

At the outset we postulated that migration from Mexico produces benefits to the United States, and that these benefits come at a cost. Our assessment leads us to conclude that the main beneficiaries are the workers themselves, both those who remain in the United States and earn higher wages than they would in Mexico, as well as those who return and reap higher returns on U.S. experience than they would have on a comparable amount of work experience in Mexico (Zahniser and Greenwood, 1997). U.S. workers who are complements in production to Mexican immigrants benefit, but we find limited evidence of complementarity. The major beneficiaries of Mexican labor are the owners of capital and land, which in California and Texas includes the vast agricultural industry that historically has employed large numbers of Mexican workers. U.S. consumers also benefit from Mexican immigration through lower prices afforded by lower unit costs for goods produced by industries where immigrants are concentrated (this includes the vast labor-intensive segments of the agricultural industry). Finally, the U.S. economy grows via Mexican immigration, although this is not a major source of economic dynamism. However, it is unclear whether and how the presence of Mexican migrants generate scale effects at the national level, although local scale effects may be more substantial.

There are also costs associated with Mexican migration. The displacement of workers who are substitutes in production is the most pronounced labor market impact, which is disproportionately borne by earlier migrants from Mexico and increasingly, by African Americans. Thus, continued immigration from Mexico may dampen the economic prospects of earlier arrivals. State and local governments that incur fiscal outlays for immigrants without adequate reimbursement from the federal government also bear the costs of Mexican migration. Education costs are particularly large, especially when they involve outlays for bilingual education

and other special services. Because education costs are incurred mainly by the young and represent an investment in future generations of workers, their present value should be discounted by the future productivity of the workers.

Another important facet of Mexican migration is that the demographic, economic and social impacts are concentrated spatially because the vast majority of earlier and recent arrivals settle in just three states—California, Texas and Illinois—and primarily in a few metropolitan centers within these states. Although residential concentration can not be assigned to either the cost or benefit ledger, this feature of Mexican migration has important social and cultural implications. The residential patterns of recent arrivals have altered the ethnic landscape of these states and in some locations, has visibly (and measurably) altered race and ethnic segregation patterns. That Mexican immigration mainly involves young workers also shifts the dependency ratio favorably, such that the burden of the elderly is shouldered by a wider base than would be the case in the absence of immigration. But, the average educational level of Mexicans is very low compared to the U.S. population, including Mexican Americans, and the weight of large cohorts in recent years have dragged down the average educational level of the Mexican origin population overall.

Residential concentration is important because it increases the visibility of the Mexican origin population and fuels anti-immigrant attitudes, particularly among those groups most likely to compete with them. Residential concentration patterns imply concentrated impacts and possibly a slower pace of socio-cultural assimilation. This is evident in the high rates of Spanish language retention, which in turn, has implications for educational attainment and labor market integration of subsequent generations.

Major Conclusions

Demographic Impacts

Although immigration has not been a major component of population growth in the past, its influence on demographic change has been increasing in recent decades. Consequently, future social and economic impacts of Mexican migration are likely to be greater because they will be compounded by higher fertility and mortality of Mexican-origin women, and the lower mortality at younger ages.

Labor Market Impacts

Analyses based on the 1990 census indicate that immigrants have little impact on native workers, except in areas of high immigrant concentration, where some job displacement and slight downward pressure on wages was evident. However,

the largest negative impacts were on the migrants themselves. Case studies indicate displacement of native workers in those sectors where that attract foreign workers. The continued flow of new migrants and their location in the same areas as their earlier counterparts, coupled with relatively low internal migration rates of persons born in Mexico, suggest that migrants from Mexico will have some difficulty in improving their economic status, at least relative to other foreign-born groups.

Impacts through Scale

Although relatively understudied in the literature on impacts of Mexican immigration, economies of scale (generated by the emergence of dense Mexican immigrant communities) can produce positive economic outcomes. The Little Village study showed that scale effects associated with densely settled neighborhoods appear to be conducive to enterprising activity even among low-education Mexican immigrants.

Welfare Participation Impacts

Mexican migrants are less likely to receive means-tested welfare benefits than their U.S. born counterparts of Mexican origin, but welfare participation rates differed by gender, headship and age. Household heads 65 and over who were born in Mexico were more likely to receive SSI in 1989 than otherwise comparable native-born heads, but this tendency may have been due to the failure of the Mexico-born heads to qualify for Social Security relative to their native-born counterparts. Welfare participation patterns and their consequences will change as a result of recent changes in welfare legislation. The new eligibility requirements may discourage the entry of some potential migrants from Mexico. The major effect of the new legislation may be the perception that the U.S. is less receptive to migrants from Mexico than previously, particularly undocumented migrants.

Fiscal Impacts

Fiscal impacts of Mexican immigration differ legal status; by state of residence; by program; and by age groups, but also depending on whether a static or longitudinal time frame is used to assess impacts; whether individuals or households are used as analytic units in calculating revenues and expenditures; and the assumptions about the size of the undocumented population. Nevertheless, because California receives the largest share of Mexican—both legal and undocumented—and because of its tax structure, it also incurs the largest fiscal impacts. Finally, the net fiscal benefits associated with immigration generally accrue to the federal government

(via federal taxes) while the net costs generally accrue to local entities, i.e., states and counties (Smith and Edmonston, 1997). Short-term impacts of Mexican immigrants depend crucially on age at arrival and schooling levels, which determine labor market options. Longer term fiscal impacts depend on income and earnings differences relative to native workers, fertility (which influences the educational investments required by children of immigrants) and state of residence (which determines the progressiveness of the tax structure).

Socio-Political Impacts

Social integration depends crucially on economic assimilation and vice versa. Although there remains some controversy about the pace at which migrants from Mexico can be integrated economically, recent econometric evidence suggests that second and third generation Mexican American men earn higher wages than their foreign-born counterparts of comparable human capital. In other words, the large wage gap between Mexican and non-Hispanic white men, and between native and foreign-born Mexican origin men, is largely attributable to group differences in levels of educational attainment and English proficiency. This is not a trivial issue, however, because Mexican migrants possess significantly lower human capital stocks than U.S. natives (including blacks) and because the demand for unskilled workers has fallen, thereby virtually ensuring low wages for those who do manage to get a foothold in the labor market.

Political impacts of Mexican immigration hinge both on rates of naturalization and settlement patterns. Low rates of naturalization coupled with the low voting rates weaken the potential impact of Mexican immigration on the political system, at least in the short run. Owing to poor data about immigrants and the criminal justice system, it is difficult to draw conclusions about the impact of Mexican migration on crime. Nevertheless, Mexicans do not appear to be more prone to crime than U.S. natives, and the major trends in crime along the Mexico-U.S. border appear not to be driven by migration. Finally, rising opposition to Mexican immigration appears to be based on mis-perceptions about the prevalence of undocumented migration in the total flow of Mexican migrants, and perceptions that Mexicans take jobs away from domestic workers. Whether right or wrong, these perceptions are quite profound in their consequences.

Research Agenda

Our study identified several areas requiring further research to better understand the demographic, economic and social impacts of Mexican migration to the United States. We conclude with a brief overview of priority questions for further research.

Demographic Issues

Mexican origin women have the highest fertility of all immigrant groups, but there is need to better understand:

- What are the causes and consequences of differential fertility of Mexican origin women in the United States?
- How do Mexican-born women and subsequent generations of native-born women of Mexican ancestry adjust their fertility behavior with duration of residence in the United States?
- How will inter-marriage patterns accelerate the assimilation of the Mexican-origin population?
- Why do internal migration patterns of the Mexican-born differ from those of their U.S.-born counterparts, and what consequences (positive and negative) follow from the low rates of internal migration?

Economic Issues

We identified several ways in which Mexican immigration differs from other flows, but data limitations constrained our ability to draw firm conclusions about various aspects of economic impacts. Further research is needed to address unanswered questions, such as:

- How do the earnings of Mexican-born individuals and those of subsequent generations of native-born persons of Mexican ancestry behave relative to an appropriate control with duration of residence in the U.S.?
- How does welfare participation and levels of welfare use change with duration of U.S. residence? What are the short and long-run fiscal impacts of legal and undocumented migrants from Mexico at the local, state and national levels?
- What is the level, nature and outcome of informal employment by legal and undocumented migrants from Mexico?
- Why are the internal migration rates of Mexico-born persons so low relative to other major immigrant groups? To what extent do these low rates of internal migration impact various outcome measures, such as earnings, employment, English language ability and other indicators of economic and social integration?
- How does the limited internal migration of the Mexican-born and Mexican-ancestry population affect residential segregation?

- What factors slow linguistic assimilation of the Mexican-born population? What are the implications of Spanish language maintenance for subsequent generations of youth? Does Spanish language maintenance retard social and economic assimilation?
- What processes undergird the negative impacts of recent migrants on employment and earnings of earlier migrants from Mexico? Is it because the earlier migrants do not respond (via migration) to labor market opportunities in other locations, do not master English, do not acquire additional education, and thus remain labor market substitutes for subsequent arrivals?
- What types of scale effects result from concentrations of Mexican migrants? Scale effects derive from the fact that Mexican immigrants consume goods and services produced in the United States, thereby contributing to aggregate income growth (although the net beneficiaries of immigrant consumption are the owners of capital). Although there is relatively little study of the consumption profiles of Mexican immigrants, such information is valuable for appreciating how the scale effects of Mexican immigration operate through demand for goods and services, including those produced within and outside of ethnic labor market niches.

Social Issues

The economic future of the Mexican-origin population hinges crucially on improving the educational profile of subsequent generations. Although the education levels of the Mexican-origin population have been improving, the rate of improvement is not fast enough to keep pace with either the gains observed for other demographic groups, or the increased skill requirements of employment.

- How do the Mexican-born and their offspring compare in this respect to other historical and contemporary immigrant groups?
- What are the determinants of naturalization propensities among immigrants from Mexico? Why are these propensities so low? Will recent changes in U.S. policies change the naturalization rates of Mexicans?
- How important is crime among the Mexican-born population, and is this problem increasing? Are recent arrivals more prone to crime than earlier migrants?

Notes

1. With assistance from Paul Davies, John McDowell, Emilio Parrado, Michael Rosenfeld and Steven Zahniser.

2. The Illegal Immigration Reform and Immigration Responsibility Act of 1996 explicitly precludes undocumented migrants from receiving most major federal public benefit programs. The Personal Responsibility and Work Opportunity Reconciliation Act of 1996, more commonly known as the Welfare Reform Act, disqualifies lawful permanent residents from receipt of food stamps and Supplemental Security Income, and prohibits immigrants legally admitted after 22 August 1996 from receiving any federal means-tested program for five years.

3. That IRCA altered the legal status of over a million Mexican migrants raises the possibility that impacts by legal status have been changed over the period we analyze.

4. For evidence about the sensitivity of conclusions about labor market impacts of migrants to level of aggregation, see Borjas, Freeman and Katz, 1996).

5. Migrant streams from Mexico are relatively small by historical standards, notably the population losses sustained by European countries during the early nineteenth century (see Massey, 1988).

6. There is some evidence that Mexican migrants are "preferred" to African American and Puerto Rican workers, especially in jobs that become "immigrant-typed" (Krischenman and Neckerman, 1991; Tienda, 1989). Some advantages of hiring Mexican migrant workers derive from well-established network recruitment hiring that benefits employers via lower search and replacement costs while also providing an informal screen on reliability.

7. For example, if the owners of capital in the United States enjoy a given gain at the expense of low-income workers, society may not wish to equally weigh the gains and losses. Such normative judgments presumably are one rationale for imposing entry quotas.

8. In the interest of brevity we focus on the three major destination states of Mexican migrants, but have produced parallel tables for Florida, New York and the major regions exclusive of these states. These results are reported in a separate appendix.

9. Another perspective of the dominance of Mexican workers in agriculture is provided by Table 2A, which presents the race and ethnic composition of industries. Taking California as an example, Mexican migrants account for nearly half of all workers in the industry compared to 36 percent of white natives and only 6 to 7 percent of Mexican natives and other migrants. Among women, over one-third of those employed in agriculture are Mexico born, compared to less than 7 percent of other migrant women.

10. Annual net demographic change stabilized around 1 percent by 1968, with modest oscillations around this level in particular years. See 1996 Statistical Abstract of the United States, Table 2.

11. These numbers are derived as follows: 12 percent of legal U.S. immigration from Mexico times a 25- to 33-percent contribution of the foreign born to U.S. population growth yields a 3- to 4-percent contribution of legal Mexican immigration to U.S. population growth during non-IRCA years. During IRCA years the calculation is based on 40 percent of legal U.S. immigration coming from Mexico, which yields between a 10- and 13-percent contribution of legal Mexican migration to U.S. population growth. Of course, this crude calculation ignores the fact that undocumented migrants were already present in the United

States and ignores the secondary impact of undocumented migration on population growth due to fertility. The latter consideration renders these estimates conservative, while the former implies that the demographic impacts occurred in years prior to those observed.

12. Bachu (1991:35) reports that the average number of children ever born was higher for women born in Mexico (2.1 births per woman) than for women born in any other country or region. On average, foreign born women 18 to 44 years old in 1988 each had borne 1.6 births at the time of the survey compared with 1.3 births for native born women.

13. Of the remaining 14.6 percent, 5.4 percent resided in Arizona, Colorado and New Mexico combined, 1.2 percent resided in Florida, 1 percent in New York, and 7 percent were dispersed throughout the rest of the country.

14. The medium immigration assumption is 820,000 per year, which is approximately the 700,000 reported by Fix and Passel (1994) plus an additional 120,000 undocumented migrants or other unanticipated refugee stream. The Census Bureau's (1996) rationale for the 820,000 middle scenario assumes 1,042,000 immigrants and 222,000 emigrants, which reflects the 1990 immigration law changes and current knowledge of emigration, undocumented migration, and movement to and from Puerto Rico.

15. This section was drawn from Greenwood and McDowell (1993) and McDowell, 1997, but with the permission of Greenwood.

16. Greenwood and Lillydahl (1984) discuss these and related data in more detail. Massey, et al. (1987, p. 173) report that among the households they surveyed, annual gross income earned in the U.S. in 1982 ranged from 281,000 to 352,000 pesos, assuming the average exchange rate that prevailed during the year. In the agricultural sector of Mexico the prevailing wage translated into 52,000 pesos per year if a worker were employed 52 weeks, which is highly improbable. Thus, by working in the United States, an individual from rural Mexico would enjoy at least a five-fold increase in annual earnings. For a sample of predominately undocumented Mexican migrants, Jones and Murray (1986) report a ratio of U.S. (i.e., average weekly earnings on latest U.S. job) to Mexican (i.e., average weekly income in Mexico) earnings that ranges from 7 to 13.

17. As of January 1997, 1,585,418 visa applications were active for North American countries. This figure represented 43.8 percent of applications worldwide.

18. The sophistication (and complexity) of the model can be increased by introducing a second good, either produced for export or domestic consumption. This extension of the model is important for understanding the elasticity of substitution of goods and laborers. However, for our purposes here, it suffices to focus on two labor groups, as this is most germane for the topic at hand.

19. This conclusion could conceivably be reversed by the presence of market distortions that result in a wide divergence between an individual's private remuneration and private marginal product. This possibility is, however, unlikely (Johnson, 1965).

20. Referring to the impacts of population growth on inventive activity, Kelley (1972, p. 20) concludes that "the scale effects of population have likely diminished significantly over time; they could well be unimportant in the contemporary setting." Kelley (p. 16) also speculates that, while probably significant in the past, "it is plausible that the positive benefits of population size through land and mineral development ... are relatively unimportant today." Spengler (1956, p. 287) makes essentially the same point as Kelley; that is, "possibly until the outbreak of World War I, immigration contributed directly and indirectly to ...the growth

of net national product and the amount produced per head. It is doubtful, however, whether this proposition remains valid after World War I."

21. For example, if immigrants are unskilled when they arrive, in the short run their impact may widen differentials between the wage of low- and high-skilled domestic workers. However, as immigrants acquire more experience, their earnings rise.

22. Skill groups are based on quartiles in a skill quantity index. Low skill refers to the bottom two quartiles based on a representative national sample from the 1990 U.S. census. High skill refers to the top two quartiles. Based on the national distribution of the skill index, data for specific metropolitan areas were formed into the various skill groups. The foreign born from Mexico tend to fall mainly in the low-skill group. More detail on the skill groups is found in the Appendix to the Commission report (see Davies, Greenwood, Hunt, Kohli, and Tienda, 1997).

23. Appendix A contains detail on all 122 metropolitan areas, whereas Table 6A and 6B report only selected areas.

24. The model upon which these conclusions are based consists of capital and the following eight labor categories: (1) low-skill native black males; (2) low skill native black females; (3) low-skill native non-black males; (4) low-skill native non-black females; (5) low-skill foreign born; (6) high-skill native blacks; (7) high-skill native non-blacks; and (8) high-skill foreign born. The skill categories are defined as discussed for the "Mexican model," and the estimates are based on 1990 census data for 225 MSAs. The simulation results are derived for a 20-percent increase in category 5—low-skill foreign born. Note that this group contains more than just low-skill persons born in Mexico because Los Angeles receives foreign-born persons from numerous countries of birth (Waldinger and Bozorgmehr, 1996).

25. Of course, the important question that no study has answered satisfactorily is whether the economic mobility of African Americans would have been higher were it not for the influx of immigrants. Unfortunately, we are not aware of any studies that can address this question in a compelling way. Several recent papers to be presented at a workshop address the question of whether and how immigration impacts African Americans specifically. This information will be incorporated in a subsequent draft.

26. Card has shown that the Mariel Boatlift, which consisted of mostly low skilled migrants, in the course of 6 months increased Miami's work force by 7% (60,000 people), yet had no perceptible impact on Miami's labor market for either natives or for previous Cuban migrants. This surprising result implies that the economic impacts of migrants are not so easily isolated to their city of entry or residence as has been previously assumed. Considering that the Mariel boat lift corresponded to a wave of migration that was a full order of magnitude larger (relative to the work force of Miami) than most of the empirical studies are able to contemplate, and that no impacts were found, Card's study raises fundamental questions about the efficacy of the econometric literature on labor market impacts of migration

27. A later study by Borjas appears to contradict that conclusion. See OECD report by Greenwood, et al., 1997.

28. Imagine adding one additional child to a school system: if the child can be absorbed into an already existing classroom, without any loss of quality in the education for the classmates, then the marginal cost of educating one additional child may be less than the

average cost. If a community received a wave of new immigrants and was forced to construct a new school building to accommodate them, the marginal cost of educating the new students might exceed the average cost per student throughout the district. Positive returns to scale implies decreasing marginal costs of services (because larger enterprises will presumably be more diversified, more efficient, and will have already made substantial capital expenditures whose cost can be born by more people).

29. Little Village experienced profound demographic succession between 1970, when Hispanics comprised only 30 percent of the community population, and 1990, when Hispanics comprised over 80 percent of all residents. In fact, by 1990, 17 of 20 census tracts were over 84 percent Hispanic, predominantly Mexicans (born in the U.S. and in Mexico). The household survey reported that over three-fourths of respondents were Mexico born. During this period, the white population decreased from 53 to 6 percent of the total and the total population of the community area rose from 62,848 to 81,155, representing a considerable increase in density (Raijman, 1996).

30. Data and models are not sufficiently refined to allow investigators to conclude that no one from Mexico enters the United States with the intention of collecting welfare, but general tendencies are clear.

31. Our discussion of demographic impacts underscored the point that California has received an increasing share of all immigrants in recent years, including undocumented immigrants from countries other than Mexico. Therefore, impacts associated with undocumented and legal migration from Mexico may in fact derive from other groups. Therefore, inferences about the current fiscal impacts of Mexican immigration are therefore exaggerated.

32. Several limitations of this study were identified by NAS, 1996, but generally conclude that this study is one of the best of its genre.

33. In fact, she seems to have causality reversed when she argues that “economic restructuring drew the growing number of new immigrant arrivals into an ever-expanding low-wage sector, where the increased immigrant concentration in a narrow tier of niches drove wages down” (p. 260).

34. Although Mexicans have among the lowest naturalization rates of all immigrant groups, recent years have witnessed a surge in naturalization applications, especially after immigrants granted amnesty became eligible for citizenship.

35. DeSipio and Rocha (1992) argued that Dukakis’ successful courting of Mexican American voters and organizations during the 1988 Democratic primaries was a key ingredient in his successful run for the nomination, especially in the Southwest. They also note, however, that once the primaries were over Latino political interests were quickly marginalized.

Impacts of Migration in Mexico[1]

Gustavo Verduzco & Kurt Unger

Introduction

Migration impacts can be defined as the effects produced by the movement of people between two places, the sending or expulsion and the receiving places. For purposes of specificity it is convenient to restrict the analysis to the effects closer to migration itself, even if in reality there are many other side effects to the migration process. For our study, we are defining migration as an essentially economic phenomenon, given the nature of Mexican migration during the whole 20th Century as the movement of labor, a movement having little to do with religious or political motives to migrate as in other parts of the world.

The literature usually treats these population movements as a positive adjustment where labor supports and complements a better use and distribution of capital in the receiving region. In modern times, labor migration invariably occurs towards regions experiencing successful economic performance. The sending region will also benefit from remittances and experiences associated with working in a more advanced environment, plus the alleviation of unemployment at the point of origin. Nevertheless, migration between countries usually faces higher constraints not found in movements between regions within a country, due to the rigidities of different legal and political frameworks. The contrast between countries such as

the United States and Mexico brings additional frictions to international migration between them.

The Nature of Migration

The first point to keep in mind are the contradictory characteristics of the economic rationale to migration in contrast to the legal apparatus aimed to refrain migration. The economic reasoning, for the most part, supports migration both from the demand of labor as much as from the supply side. The legislation within the recipient country, in this case the U.S., limits the movement of foreigners. There are also, of course, many other social, cultural and demographic tensions and implications to consider given the mobilization of people under consideration, which involves the relation between two societies strongly different in their backgrounds.

Our aim in this chapter is to determine the effects in Mexico, in general and also specifically, resulting from being influenced by these labor movements. To this end we have to review the many concerns expressed by analysts of migration effects, both the positive and the negative impacts, but keeping at the center the economic preeminence of the phenomenon with labor as an important factor of production, and then the legal, cultural and demographic issues that may help us reach a better understanding.

A Temporal Dimension

To address the effects or impacts of migration on each country, it is necessary to consider several dimensions. One crucial dimension is time, given the very old labor supply and demand interaction embedded in the operations of each country, an interaction subjected to substantial variations along time.

Migration flows have varied in size, intensity and characteristics over the various periods of this century. The effects have to be estimated in reference to the specific period and context which corresponds to each country. However, these effects have to be seen not only as concrete measures or estimates in a certain point of time, but also pertaining to the dynamics of a very long labor interaction process.

International Economic Reorganization

It is well known that the economic pressures for restructuring have been experienced in over recent decades by every economy, including the Mexican and the United States economies. The U.S., as a wide and complex economy, has experienced a variety of sectoral and regional strategies. One of these strategies

has involved the hiring of low skilled labor at very low wages in order to remain competitive in certain agriculture activities (particularly evident in California) and in some services (Escobar, A., F. Bean and S. Weintraub, June 1996).

For Mexico, on the other hand, the result of trade liberalization, adjustment and privatization during the last decade or so has been a huge increase in the levels of unemployment and the search for all kinds of complementary incomes to finance basic family survival (Cortés, F. and R. Rubalcava, 1995). Open trade has also meant the successful recovery of certain agriculture activities, in particular those for export, and it has also channelled substantial new investment into subcontracting (*maquiladoras*) and a few other industrial and services activities. These trends will shortly show up in higher local demand for labor in Mexico, even if in some cases (as in the first direct effect of *maquiladoras*) this is at the expense of employment in other locations in the U.S. itself.

The North American scene has shown initiatives beyond the usual individual country moves. Most noticeable has been the U.S. initiative to incorporate Canada and then Mexico into NAFTA. This can be understood as a common strategy to better compete against Europe and Asia. It is most evident in the immediate strengthening experienced in the economic ties of the three NAFTA countries, most clearly shown in trade and investment statistics. And it is in the context of economic changes and the recent evolution of migration, the "demand-pull supply-push" interaction, where recent effects can be located.

Migration Flows: Temporary vs Permanent Migrations

The characteristics of migration flows add important considerations to estimates of impacts. Among the total so-called "migrants," there are two major groups, those becoming permanent residents of the U.S. and many others that come and go, some of them continuously along their productive lives. The latter group may experience the journey only once or a limited number of times, while some others may do it regularly. These patterns of migration impose obvious differences in the estimates of impacts or effects, be these economic effects, labor, or demand for public services. Though there are some preliminary estimates to distinguish the two types of migrants, in practice it is extremely difficult to estimate separately the effects due to each.

According to the survey EMIF (Encuesta de Migración a la Frontera Norte de Mexico), the annual flow of labor migrants travelling to the U.S. in 1993 and 1994 was around 800,000 individuals (Corona, R. and R. Tuirán, 1996). This is to say that any estimate of impacts would need to take into account the different behavior of this group of labor migrants, different in many respects to those residing permanently in the U.S.

Another strand to differentiate impacts is the legal status of the migrating flows. This is important in itself and also in respect to the workers' own perception of their labor competitiveness. In this respect, it is well known for instance that IRCA transformed almost automatically an important proportion of migrant flow as legal or documented migration, which then may have a different kind of effect accordingly. In practice, however, it is difficult to distinguish the effects or impacts of one group to the other due to information limitations, even when we may anticipate large differences in many respects.

The Levels of Analysis

Impacts have to be referred to the level where they are materialized. Spatially, there are three levels: national, regional and local. While at the national level impacts may be small in many respects, at the regional and local levels the impacts of migration may be extremely important. This can be as valid for certain regions in the sending country as for some of the states and counties that concentrate the flows in the recipient side.

It is well documented that there is a very large concentration of Mexican labor migration to the U.S. in the southwest, as well as to certain areas or poles mainly restricted to the states of Illinois, Oregon and Washington. Some other well dispersed places exist, but they account for minor proportions.

Another distinction has to do with the sector where migrant labor is employed. Mexican labor in the U.S. is mostly concentrated in agriculture, in particular in the production and packaging of fruits and vegetables, and some others are in the clothing industry, construction and certain services for buildings, gardens, tourism and what have been called the "ethnic industries." Even if the evidence indicates that the most recent Mexican migrants are predominantly in unskilled and low paid jobs in these kinds of activities, it is necessary to account as well for other groups of Mexican migrants in the past that followed more conventional employment trajectories given better conditions in the demand side, both conditions of the labor market and of economic prosperity in general, that were more favorable to that end.

On the Mexican side there is also a heavy concentration of not so many localities (municipios) with large migration intensity. These are mostly located in five states: Jalisco, Michoacán, Zacatecas, Durango and Oaxaca. These are the places where Mexican impacts of migration to the U.S. are likely to be apparent, at least in comparison with other non-migrating areas. Other characteristics relevant to estimating effects in these *municipios* is that more than one half of them (57% to be precise) are rural places (less than 20,000 inhabitants), and very few of them (only 1.7% to be precise) have more than 50,000 inhabitants.

The predominantly rural origin of the Mexican migrants explains their employment in the least skilled jobs in the United States. That is a very different case for Mexicans that migrate *within* Mexico, who tend to be more urban in origin and have better skills.

All the considerations above imply that we have to estimate carefully the impacts for each country according to the level and sector of activity, as well as other factors mentioned previously.

The Stylized Facts

First, we are dealing with two neighboring countries sharing a very long border and where the presence of Mexicans was well established before the west ward expansion of U.S. settlers in the previous century. This explains the important groups of Mexican origin in the southwest of the U.S. well before the migration moves of this century, a situation that has undoubtedly facilitated the assimilation between the two types of populations.

Early in this century, closeness between the two countries also facilitated migration flows. During the decade between 1910 and 1920 an estimated 890,000 Mexicans moved to the U.S. due both to expulsion and attraction forces. The expulsion factor was mainly the Mexican Revolution that took preeminence in Northern Mexico; but at the same time, Mexican labor was welcome to help in the extension of the railroads and in agriculture in the U.S., given the shortage in U.S. labor due to this country's participation in World War I (Hall, Linda, 1990). Even taking into account that few of those remained in the U.S.,[2] the next decade of the 1920s registered the approval of legal residence for 459,287 Mexicans, a total 3.2% of the Mexican population at the time.

As a counterflow, the economic difficulties of the 1930s generated the repatriation to Mexico of 345,000 Mexicans (47% of all those legalized since 1900). This move created substantial problems in the absorption of labor in certain regions of Mexico, something that quite likely accelerated the Cárdenas agrarian reform of the 1930s as illustrated in some ethnographic studies.

Next, the U.S. entry into World War II demanded again the support of Mexican labor of low cost (Fisher, 1953), giving raise to a total 4.6 million legal contracts to Mexicans in the U.S., the so called *Programa Bracero*. In spite of the relatively high number of contracts (equivalent to 209,000 a year), those opting to reside permanently in the U.S. were only a 12% of the total number of contracts granted. These are the very same years when Mexico enjoyed very successful rates of growth, the period of the "Mexican miracle," which translated into better living standards for many in Mexico due to improvements in education, health and other social benefits despite high rates of population growth.

In latter years, particularly during the 1970s and 1980s, the number of Mexican residents in the U.S. was increasing, at the same time that temporary migrants, both legal and undocumented, were also increasing. These years represent both the end of the "Mexican miracle" and the change in the direction of migration laws in the U.S. to restrict earlier acceptance of migrants.

The most recent period in the 1980s has developed more critically certain contradictions for the two countries, because the Mexican debt crisis of 1982 acted together with the approval of IRCA in 1986 to push into the legalization and, quite probably the settlement also, of a considerable number of Mexicans (2.24 million between 1986 and 1992), on top of the flow of recurrent temporary migrants between the two countries.

Some Impacts at the National Level in the Two Countries

The brief consideration above to the changing circumstances of labor migration during the 20th Century puts under perspective not only the magnitude of the flows in different periods, but also underlines the changing conditions over time affecting the interaction of supply-demand for labor, which in turn imposes different effects for each country in the different periods of attention. There have been periods in the past when migration was even more important than in recent years.[2] For instance, from the Mexican perspective, the loss of 3.2% of total population during the 1920s has probably been the most important demographic loss, not only in relative numbers, but also in the sense that the migrants were mostly relatively skilled middle class workers accounting for a very important share of the country's extremely scarce human capital (Verduzco, 1992). It is most unfortunate that we do not have more detailed studies of this kind.

Some speculation can still prove helpful. The loss through migration in the 1920s, is most significant if one considers that during the 1910s the Mexican Revolution resulted in the loss of 16% of the Mexican population, most of them part of the work force (Ordorica and J. Lezama, 1993). By the same token it is likely that the arrival effect of these Mexican migrants was not as important for the U.S. if considered on a national scale, but it certainly was considerable at the regional and local levels, especially in the southwest. And also the economic effects of the Mexican migration flows will vary according to their countercyclical contribution to the U.S. economy, say during the immediate post war 1920s and the very hard 1930s. We know that estimates of this kind are scarce and hard to get but they can certainly be postulated at high probability rates.

The impact on the U.S. of Mexican migration is undoubtedly present today in all spheres—cultural, economic, demographic and political. The contributions of

many well settled and assimilated Mexican-American communities and individuals are in evidence and well appreciated.

For Mexico, the *Programa Bracero* was most important between 1942 and 1964. It was particularly relevant for most of the rural communities on the center-west coast and northern Mexico as it has been extensively documented on studies of *pueblos campesinos* by both Mexican and U.S. scholars (Foster, 1948 and 1967; Beals, 1946 and 1962; Belshaw, 1967; Acheson, 1964). However, the extent and impact of migration flows during those years was very different from what seem to be the characteristics of present migration. On the one hand, Mexican labor at that time took essentially seasonal agricultural jobs, and few of those workers became permanent residents of the U.S. On the other hand, the Mexican economy was growing fast and did not show the kind of structural problems to create productive employment that we face today. In sum, a plausible hypothesis is to assume that migration in those years was due mostly to demand forces (the *Programa Bracero*), even if remittances and other positive externalities were also important to support the Mexican modernization in agriculture well in place during those same years.

The Challenge to Focus on Impacts

To properly estimate current effects or impacts of Mexican migrants, we need to take into account the very complex sum of economic, social and cultural interrelations that has amassed in both countries over the long experience of migration. The challenge is most important because our interpretations will have to remain consistent for future data comparisons.

Specific Criteria on the Impacts in Mexico

First, it is most important to consider both the number of persons who participate in the phenomenon of migration and the manner in which they participate in it.

Earlier we saw that the volume of migratory flows has varied considerably throughout the century, and therefore, for that reason alone, the impacts should also be different in the regions of origin during different periods.

Furthermore, the types of migration, whether temporary, recurrent or permanent, make the impacts stemming from each type equally different. It is not the same when most heads of families in some community have gone to work for one or two seasons in their lives to the U.S. as when a significant portion of the economically active population migrates in a recurrent manner; or when, after a few years, entire families in one locality move permanently to the United States. These are therefore diverse circumstances that influence the types of impacts that may be seen in the places of origin, and for that same reason it is important to be able to determine

them clearly, since both the implications and interpretations of those facts could vary enormously.

Other factors necessary to examine include the regions and localities of origin of migrations and whether those places have gradually changed over time, since the impacts would be different depending on the concentration or dispersion of migration, as well as on the years of exposure to the phenomenon. The literature shows varied effects along both dimensions.

It would not be the same if we found that migration came from all points in the country, that is, following a pattern of geographical dispersion, as if it were concentrated in specific areas. In the first case the regional impacts would probably be more difficult to discover than in the second. If various patterns coexisted, this would also pose different analytical challenges.

For the time being, we know that migration from Mexico to the United States has been taking place for many years. We also know that although the flows of origin have continued to be concentrated in some states of the country, there are now some new types, and that urban places of origin have increased, as have female and family migration.

We also have information showing that both the volume and the type of migratory flows have varied throughout the century. The years of the *bracero* agreement were the period when it was clearer that migratory flows had a merely seasonal nature and were limited almost entirely to the rural sphere in both Mexico and the United States.

In other pages we mentioned some of the overall impacts resulting from migrations in both countries. Below we will present different types of information that will enable us to situate more clearly both the circumstances that have a bearing on the impacts of migration, and the advances in knowledge that exist as a result of different research projects that have been carried out. We will begin by stating some of the general characteristics of migratory flows based on the differences observed in the municipalities of origin. This overview will give occasion to talk later about the variation in the impacts of migration in the different contexts of the country.

Municipalities of Origin of Migration

Of the 2,428 municipalities in the country, 62% show some degree of "migratory activity" to the United States, although 18% have extremely low levels[3] (see Table 1).

But looking at the above distribution by regions we find that in the southeastern states (Chiapas, Tabasco, Campeche, Yucatán and Quintana Roo), 66.5% of municipalities do NOT participate in that flow of migrant working population to

Table 1
Migratory Activity in the Mexican Municipalities by Regions
(Porcientos)

% EAP	Border	North	West	Center	Southeast	Country
0	10.2	5.5	2.5	39.7	66.5	38.0

	(abs. 273)	(abs. 182)	(abs. 313)	(abs. 815)	(abs. 817)	(abs. 2404)

*Migratory activity-=Percent of migrants per Economically Active Population in the municipality.

Source: National Survey of Demographic Dynamics (ENADID 1987–1992).

the United States. It should be recalled, however, that development levels in those states are very varied, from very poor to very rich.

Furthermore, in the central states (Oaxaca, Veracruz, Guerrero, Puebla, Tlaxcala, Hidalgo, Querétaro, State of Mexico and Morelos), 33.8% of the municipalities do NOT participate. By contrast, in the border states only 10.2% do NOT participate, and in the western and northern states practically all the municipalities have some participation.

In the country as a whole, the states with the least participation are Tabasco, Chiapas, Veracruz, Yucatán[4] and Quintana Roo. But in addition, in the state of Oaxaca, 65% of the municipalities do NOT have any migratory activity, and therefore we have a contrasting situation there: in the last few years it has become a state of migration to the United States, but nevertheless the majority of its municipalities are not connected with that movement.[5] Moreover, the municipalities in that state involved in migration are dispersed throughout the different areas of Oaxaca's territory and it is only possible to speak of a relative concentration in the Mixtec region and slightly less in the Central Valleys, where the capital is also situated.

Let us now see how the municipalities are distributed according to greater and lesser intensity of "migratory activity."

In the first place, of all the country's municipalities, only 4.5% have "high" or *intense* migratory activity, a circumstance that probably situates the phenomenon of the country's "recurrent" migration in those places, since the reference of the indicator used for the Economically Active Population (EAP) of a municipality tells us, in those cases, of a situation that implies a structuring of the migratory

process that can only take place over many years.

Similarly, of the municipalities with "high" migratory activity, 80% are municipalities with a population of less than 20,000 inhabitants, which means they are very rural municipalities, and only one of them (Jerez, Zacatecas) has more than 50,000 inhabitants.

By contrast, we find that of all the municipalities in the country, 43% have "low" migratory activity and 17% medium. In these cases, 56% are municipalities with less than 20,000 inhabitants and only 17% have more than 50,000 inhabitants, which means that we can characterize the phenomenon of migratory activity as being closer to rural than urban conditions.[6]

Of the municipalities with "high" or *intense* migratory activity (109 municipalities), a majority of 88% are found in 9 of the states with the most migration: Jalisco, Michoacán, Guanajuato, Zacatecas, Durango, Chihuahua, San Luis Potosí, Guerrero and Oaxaca; but 48% are found in only three states: Jalisco, Michoacán and Zacatecas. This gives us a clear idea of the places where this type of municipalities are concentrated.

In summary, we find that the phenomenon of *intensity* of migration does not occur throughout the length of the republic, but is limited to only 4.5% of the country's municipalities, and of these, half (48%) are found in only three states: Jalisco, Michoacán and Zacatecas. We therefore need to be very careful with interpretations of the phenomenon of migration, especially when these are made on the basis of community studies, as the above information shows us, on the one hand, a dispersion of the phenomenon in general terms in the country, particularly from the central states towards the northern and border states, but, on the other, we can see a very strong concentration of the municipalities with the highest *intensity* of migration in few states, mainly in the west.

Variations in the Impacts

In conclusion, from the point of view of the impacts of migration on the places of origin, the above information shows us that since there is great variability in the phenomenon of migration in the country, the analysis of the impacts should take that consideration into account. We will talk about this further on.

Summarizing what has been analyzed so far, we find in the first place that a significant increase in the phenomenon of migration to the United States does seem to have occurred in the country, since there is migratory activity in 62% of municipalities. It is concentrated in a few states and areas of those states, mainly in the west and north (except the border states), as was pointed out earlier.

In the west we also find the majority of the municipalities where migratory

activity is highest of all. These include municipalities which for reasons of categorization fall within the limits of what we have qualified as *intense* migration (more than 25% of their Economically Active Population—EAP—involved in migration), as well as the municipalities in which more than 50% of the EAP have migratory activity to the United States. These municipalities have high migration since over 50% of their Economically Active Population went to work in the United States between 1987 and 1992. They total 23 municipalities and 19 of them (83%) are in Zacatecas, Michoacán and Jalisco. But of these 23 municipalities, only 3 have more than 20,000 inhabitants and the 23 as a whole have an average of 11,155 inhabitants. This gives us an initial idea of the type of municipalities involved.

The information also shows very clearly that the majority of the more urban municipalities, that is, those with more population, especially in the west and north, also have migratory activity, although with low levels. This is a fact which, in addition to coinciding with other information sources such as the Survey on Migration to the Northern Border (EMIF), makes it necessary to pose new research questions, since in fact we still know very little about the meaning of migration to the United States from these contexts, although further on we will try to point out some of the better known features so far. But having put forward these considerations, clearly the more rural municipalities with a population of less than 20,000 inhabitants predominate and for that reason they should be the prime object of our analysis with regard to the impacts.

And if we recall what we have seen in relation to the municipalities where there is *intense* migration, all of them, with the exception of Jerez, Zacatecas, have less than 50,000 inhabitants and most do not exceed 20,000 population. Let us also recall that only in a few cases do those municipalities form part of microregions within the states.

These different characteristics of the municipalities of emigration make it necessary for us to be cautious when speaking not only of the causal factors of migration, but also of the impacts on those places.

Municipalities with a Tradition of Intense Migration

We should also differentiate between municipalities or communities with a "long tradition of migration," as well as those that have a "migratory tradition," and those that have been incorporated into the migratory flow recently or relatively recently.

In the first of these, that is, those with a "long tradition of migration," the factors that had a bearing on the start of the migratory flows occurred many years ago and are unknown to us. Nevertheless, the effects of those successive migrations have gradually accumulated in a different manner over time, in such a way that

*Asterisk denotes communities with “intense” migratory activity.

what we can observe now is a different situation from those that prevailed in different periods and which gave rise to separate flows, probably also with different purposes according to each period. In these cases, what we are surely observing at present, if the flows have continued to be *intense* and uninterrupted, is their continuity, and we should therefore consider them thus to observe the factors that continue to

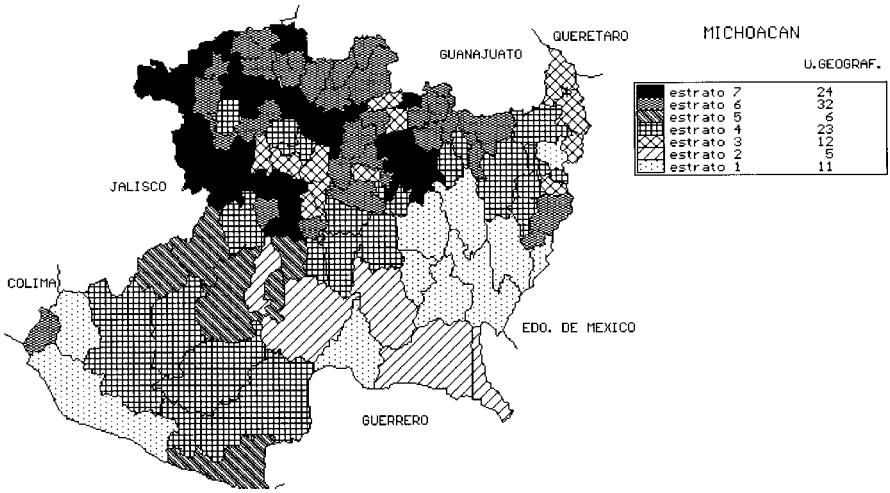

Figure 1. Density of Migratory Activity

further the migrations, as well as if we had to observe and interpret different effects of the migrations, since the recent impacts have changed on the basis of the achievements or of meeting the needs of earlier years, partly as an effect of the migrations themselves. For that very reason these types of places should be differentiated from those with recent flows, since in some the purpose of the migrations will be different from those where the migrations have been taking place for many years.

By the best known studies, cases of this type would be those exemplified by the studies carried out in the town of Jaripo (Fonseca, O. and Lilia Moreno, 1984); in Gómez Farías (López, G., 1986) and the one called Chamitlán (Massey et al., 1991), towns in Michoacán that have had continuity in the migratory process without interruption for a long period of time.

According to what is reported, migration in those places (and its effects) has not allowed appropriate or sufficient conditions to be met in order to end or reduce the dependency on migration to the United States. One author therefore states: "Migration is self-perpetuating because of the new consumption needs created by expectations of life and by the permanence of the variables that condition migration" (López, G., *op. cit.*, p. 109). This is therefore a form of insertion, among others, into the migratory process.

But another variable in this type of migration is the one presented in some of the studies by Robert Kemper (1995 and 1981) for the town of Tzintzuntzan, Michoacán. If we had looked at migration in this town at just two moments in time (in 1960 and 1980), we would think that there had been a continuity of the process.

There, however, migration has been interrupted: during the *bracero* contract it included practically all heads of families but it was suspended almost entirely during the 1960s and 1970s and was then directed en masse to Mexico City and other cities in the country. During the 1980s, migration to the "North" appeared again. Something similar appears to have taken place in the other lakeside towns of Pátzcuaro, as reported by Lise and Pietri (1976) until the 1960s, as well as Castile (1974) and partially by Beals (1946 and 1962) in the Tarascan Meseta of Michoacán for those same years.

By contrast to the first type of cases, here we find first a mass migration by heads of families at the end of the *bracero* contract, together with the extensive establishment of information and support networks. Then these flows ceased and were oriented mainly to Mexico City, and began again later to the United States during the 1980s.

As expressed by the same authors, the impacts of migration have been different partly because conditions in each period have varied, but also because the occupational composition of the migratory flows has been partially transformed in the different periods. The latter is important because although at times the flows might not diminish in volume or proportion, what has been observed are differences in socioeconomic groups that act in accordance with a specific purpose; the impacts may therefore also vary.

In these cases, as distinct from the previous ones for the state of Michoacán, not only was there a rupture in the migratory process to the United States, but also it was replaced by one of internal migration and then the orientation to the "North" was resumed just a little over a decade ago.

In our municipal information, the municipalities of the first type mentioned (Jaripo in the municipality of Villamar, Chamitlán in that of Chavinda and Gómez Farías in that of Tangancícuaro) offer the most *intense* levels of migratory activity in the entire country (above 50% of the EAP),[7] while the municipalities of the lakeside areas and the meseta appear in the "medium" and "low" levels. These are some examples of the care we have to have both to talk of the causal factors of migration, and if we have to analyze its impacts.

Municipalities with a Tradition of Migration

Apart from the municipalities or states that have had an *intense* participation in migration over time, we also have others in relation to the states that have had some relatively significant degree of migratory participation, although to a lesser extent than the previous ones. This is the case particularly with some of the border and northern states.

The low presence of migrants from these states according to information sources of the past, leads us to think of the hypothesis that the expansion of the agricultural frontier towards the north with the creation and expansion of important irrigation districts constituted an attraction for internal rather than international migrations. Let us recall the importance of the irrigation districts of Mexicali, of Sonora, Chihuahua, Coahuila and Tamaulipas in relatively recent times for the settling of the north of Mexico. It has been a process in which the opening up of lands and the settling came first, followed by agricultural modernization as of the 1950s.

However, perhaps because of the proximity of the border and fluctuations in the changes that were taking place, those states have had international migration for many years and therefore can be considered states with a "tradition of migration," even though their participation in the overall flow has been low.

We thus have another variable introduced which, unfortunately, we only know superficially. We do not know, for example, whether there is a corresponding agricultural labor force to these irrigation districts on the other side of the border; nor do we know whether the agricultural crises on this side were reflected in an increase in migratory flows from those states. We know in general that the migrants from those places have been relatively few, although we also know that their participation in migrations is long-standing.

In the regionalization used here, it appears that the states of the "north" have a proportion of municipalities with *intense* migratory activity that is very similar to the situation of the western states. This is due mainly to the states of Durango and especially Zacatecas, which contribute with 97% of the municipalities of the north in that category.

In fact both in the north and in the border area there is and there always has been migration but it appears to remain at medium and low levels and it would therefore be important to know the purpose of these flows in the different areas of those regions, as well as in rural and urban localities. That information would be most useful to be able to situate the type of impacts on those regions whose characteristic is having a tradition of migration which remains at low levels.

Municipalities of Recent Incorporation into the Phenomenon

The best known states involved in migration are Oaxaca, Guerrero, Puebla and Morelos, although there is still very little information on this phenomenon in those places.

In Oaxaca, which is the best known state, seven municipalities (1.2%)[8] have *intense* migration, and in the rest of those that do have migration, "low" migratory

activity predominates. Let us also recall that 65% of the municipalities in this state do NOT participate in this type of migration.

We know from the work of anthropologist Abraham Iszaevich (1988) that in one of these municipalities with intense migration (San Lucas Quiaviní), migratory flows to the United States began to increase in the early 1960s and eventually included 65% of adult males in the community. Moreover, in the seven communities he studied, there were different patterns of migration both to other places in Mexico and to the United States. Unfortunately we know almost nothing about the migratory situation in this state, which is particularly complex, not only because of its size, but also because of its cultural heterogeneity, since more than 10 important ethnic groups inhabit the state.

In other municipalities with recent migration, municipal information shows that migration to the United States is partially extended to all the country's states, although with low levels of intensity and with very limited participation in the majority of nontraditional states. In these cases, there is practically a total lack of information, as it was not even suspected that the phenomenon existed in the majority of those places.

In the three categories indicated above we have major differences that we should consider in order to situate the details of the phenomenon of migration in a manner appropriate to the conditions in which it occurs. This is also the path that will enable us to better understand aspects related to their impact.

The Rural and the Urban

In the cases of most intense and semi-intense migration, rural municipalities predominate over urban ones, although there is migration from practically all the municipalities that have urban populations. Therefore, even from this perspective, it would be observed that urban migration to the United States would probably already have major importance.[9] The Survey on Migration to the Northern Border (EMIF) reported that 56% of the flow came from urban localities—of more than 15,000 inhabitants—(Corona, 1996). But, unless this movement of people can some day be measured more accurately, it is clear migration of urban origin is more important now than before, and it would therefore be necessary to study in depth the implications of such a change.

Until now the most accurate study of migration to the United States has been carried out almost entirely from the rural point of view because the evidence was easier to analyze. In fact very few studies have analyzed this phenomenon from an urban perspective, as we will see further on. For the time being it is a limitation that does not allow us to understand the logic of labor movements of an urban work force that goes to work abroad; and even less to

think of specific impacts beyond a few general considerations following from the few existing studies.

Migrations and Development: National or Community Viewpoint

Earlier we saw that migratory flows to the United States have varied enormously over the century due to diverse circumstances in each country. For Mexico as a place of origin of migration, variations in the flow should be more or less in keeping with the type of changes that have taken place in different periods. Something similar should occur with the impacts, since as has continually been repeated in the studies, people do not simply leave to work as an end in itself, but with specific projects and goals. Therefore, following this same logic, it would be consistent to think that, depending on the specific contexts of migrants and according to the community and regional circumstances of each period, the migrants established their own goals in each period.

The above considerations point to various criteria that would be important to take into account when talking of the impacts of migration on the places of origin in Mexico.

Similarly, we have presented an overview of the presence of recent migratory flows in the country, as well as on the places where there is a greater presence of the phenomenon. This will enable us to interpret more appropriately the information that exists on the impacts based on the different studies that have been carried out in different periods.

Different Priorities in Research

We should note, in the first place, that unlike many of the studies carried out in the United States, in Mexico the topic of impacts has not been a priority—at least not from the same viewpoint, nor with the same insistence. Secondly, the majority of the studies deal with migrants and migrations from the rural sector, which although consistent with the greater presence of the phenomenon in those places, bypasses the view of the impacts on the diversity of urban localities where migration also exists. Thirdly, most of the studies, particularly the better known ones, have been carried out in two of the states with the most migration in the country (Michoacán and Jalisco) and several of them in communities in the municipalities with the greatest intensity of migration in the entire country. And although it is logical that it should happen, this implies certain limitations, at least from the point of view of the suitability of having a more comprehensive and complete knowledge of the phenomenon, especially when we know that recently it has become dispersed to almost the entire country, although with a low presence.

Among the studies carried out, the community studies of anthropologists or of an anthropological nature stand out. In those types of studies, it has been more common that the purpose of the work did not have the specific intention of studying migration, but rather the community life of *campesino* villages. The encounter with migration to the United States has been a finding that, owing to its magnitude and importance in the communities, has had to be detailed more carefully. That is why those studies are mainly geared to an ethnographic description of the life of communities in accordance with the most conventional methods of anthropology. These are followed in number by other studies of a sociodemographic nature whose information comes mainly from surveys applied to the population, sometimes to a single community or city, or to areas or groups of communities or cities, based on a sample that in some cases has been statistically representative and in others not.

Another characteristic in all cases is that the studies were carried out during different periods, a situation that also makes us be cautious with the interpretations, since we would have to situate the information according to the conditions of the appropriate spatial and seasonal contexts.

In speaking of the impacts, the authors tend to favor those that are a consequence of monetary remittances, that is, of the money sent or taken by migrants themselves to their communities. Some researchers, however, have also focused on the topic of the noneconomic effects of migration, although few have delved more deeply into this point.

The authors' intentions have frequently been to interpret the effects of both monetary remittances and work experience in the overall process of change in the communities studied. We should also be cautious, however, in this regard, since the authors do not always give an account of socioeconomic processes in the communities they have studied.

Jorge Durand (1994) also states an important fact in presenting the best known community studies. These include 25 authors and almost 37 communities, of which 30 are in Michoacán and Jalisco, 3 in Guanajuato, 3 in Oaxaca and only 1 in Zacatecas.

Despite the above-mentioned limitations, we believe that the series of research projects carried out in Mexico by both Mexicans and U.S. researchers can contribute important and useful knowledge on some of the effects or impacts of labor migrations in Mexico.

Monetary Remittances

The topic of remittances is perhaps the one that has received the most attention among the economic effects of migration. This is partly because it can be measured. The justification is greater in this case since wages are considerably higher in the

United States than in Mexico and there tends to be a differential between the peso and the dollar in favor of the latter which leads to a special appraisal in this regard.

Although the importance of monetary remittances has been known since the 1920s (Gamio, 1930; Taylor, Paul, 1932 in Durand, J., 1994), it was not until recently that researchers began to be concerned about the topic and to try to record the amounts in some way. The estimates of remittances reported in the literature generally allude to two levels: estimates of national coverage or estimates at the level of very specific communities in which case studies have been made.

Frequently, based on specific research projects, researchers have attempted to make more global calculations of the remittances sent by all Mexican migrants (Díez-Canedo, 1984); García y Griego, M. and F. de los Ríos (1985); Massey and Parrado (1994); Lozano, (1993). However, whether because of the community orientation of many of those studies, or because of the broad suppositions on which they had to be based, those calculations have been useful only as preliminary approximations during times when more accurate estimates were not available. Subsequently there have been other more complete estimates based on information from surveys with greater coverage, such as the survey carried out by CENIET, and more recently the Survey on Migration to Mexico's Northern Border (Corona, 1996).

In recent years Banco de México (the Central Bank) has designed a complex methodology together with a strategy of very broad coverage in order to be able to measure the inflow of dollars from Mexican migrants working in the United States.

Based on this methodology, and having reviewed the different measuring tests carried out, Fernando Lozano has produced two measurement exercises, trying to make up for the limitations of the different efforts, including the most recent ones, such as those carried out by Massey and Parrado (1994) and Corona (1996). This last work of Lozano's was carried out at the request of the commission that prepared the binational study (Lozano, 1997). His estimates are very close to the latest ones from Banco de México: US$3.867 billion for 1995 compared to the bank's estimate of US$3.672 billion.

Viewed from a national standpoint, the importance of remittances may seem moderate if we compare them with earnings from exports of goods, since the remittances sent by migrants barely represented 5% of the total value of exports in 1995. Nevertheless, they were equivalent to 57% of foreign investment that year. It should be recalled, however, that during the last decade remittances had a much greater relative importance when the economic context was also different, and remittances were in fourth place in foreign-currency inflows from abroad.

In view of the above and following the nature of geographic concentration of the phenomenon of migration, it would seem more useful to evaluate it from a

regional point of view. On this scale the importance of remittances is much greater, particularly if we bear in mind that the majority of municipalities of origin are predominantly rural.

Lozano's estimates are perhaps more revealing from another perspective, that which distinguishes between permanent and temporary migrants. The most important implication of his estimates is the large proportion represented by remittances from permanent migrants: 64.7% of total remittances. If the well-known tendency for permanent migrants to reduce their remittances to their area of origin as time goes by is proven, the importance of the remittances is destined to decline even more in the future.

Now, as we have seen when reviewing the municipal figures, although migration is present with different levels of intensity throughout the country, it is mainly concentrated in the states of the west and north, but especially in the former. From the point of view of remittances this would mean, at least in theory, a greater importance of same in those states and, within them, in the areas and communities in which the phenomenon of migration has intensified more, as we saw in earlier pages.

Clearly, in those areas in particular, the economic benefits of migration are most important, since the average income from remittances is equivalent to the average income of households in a context in which only 40% of households reach those levels of income (Papail and Arroyo, 1996). Also, remittances and other forms of assistance from migrants have been channeled over the years into providing support for certain agricultural activities, as well as for countless works such as parks, schools, churches, roads, street paving, introduction of drainage, etc., in a great many communities in those regions.

Similarly, the indirect effects of remittances should also be mentioned. These can be calculated, although in a partial and limited manner, on the basis of economic simulation exercises. Edward Taylor (1996) calculates that the greatest multiplying effect of remittances takes place in rural households whose consumption and spending patterns favor goods produced domestically with labor-intensive technologies; by contrast, when remittances reach urban households, the multiplying effects are less for Mexico because consumption patterns in those places include a larger number of imported goods. Taylor calculates that each dollar sent to Mexico by migrants could translate into an increase of between US$0.30 (30 U.S. cents) and US$0.40 (40 U.S. cents) in the income of farmers with small landholdings.

Nevertheless, as the United States economy becomes more integrated, the multiplying effects of remittances are likely to become smaller, since production in Mexico will respond more to demand in the overall North American market and less to demand only in Mexico.

Remittances and the Households

Strictly speaking, the most direct impact of remittances in dollars occurs in the households where they are received, depending on the amounts sent and the circumstances of each one. Secondly, the community can benefit more or less, depending on the number of households with migrants and of members working abroad, and there will also be greater benefit when the community can retain a substantial part of the multiplying effects of the demands stemming from the first outlay. Similarly, the impact will depend on whether the migratory pattern in the community is occasional or recurrent, that is, whether households have members migrating with a regular annual or biannual frequency, or whether migration takes place only occasionally, once or twice throughout people's entire life. Migration that becomes permanent is also destined to reduce its contributions.

These different types of behavior in fact occur in the myriad communities involved in the migratory process.

There follow some examples. Paul Taylor (in Durand, 1994) reported that during the 1920s there was a mass migration from Arandas, Jalisco, which included the young men of all social classes except landholders and wealthy merchants, but without excluding their sons. In 1923 the income from the 200 "northerners" from the town was $75,000 pesos, or the equivalent of US$375 per person (Martínez, T., 1985), a figure which in those days was not negligible.

Robert V. Kemper for Tzintzuntzan (1981 and 1995) and Castile (1974) for Cherán, both towns in Michoacán, affirm that almost all the young men in the community enrolled at some point in the Bracero Program, although afterwards they did not continue to go but changed their destination from the United States to Mexico City, although as was mentioned before, during the 1980s the emigration to the "north" began again. Currently, Kemper states (1995) that 200 families from Tzintzuntzan are living in Mexico City and around 150 in the United States, aside from the fact that 362 persons are living temporarily outside the community in Mexico City, Morelia and the United States.

In four communities of Michoacán and Jalisco, D. Massey et al. (1987) point out that of all migrants, between 15% and 25% had left to work in the United States 4 or more times. These would be the "recurrent" migrants.

Jorge Durand (1994) affirms that on average in the 11 communities in his study (in Michoacán, Jalisco and Guanajuato), 54% of the migrants had only made one journey in their entire life. Something similar is stated by Gustavo López (1986) for the town of Tangancícuaro in Michoacán, when he says that approximately 60% of the adult population had migratory experience, that is, that they had gone at least once.

In Los Altos (the highlands) of Jalisco, Juan Luis Orozco (1992:401-2) mentions three different profiles of migration in his communities. In Corralillos, 36%

of the sons had gone to work in the United States, while in the village of Los Dolores 21.4% had left and in El Refugio only 4.2%.

For Zamora, also in Michoacán, it is reported that 14% of the city's working population had migratory experience but only 19% of them were "recurrent" migrants who had gone four or more times (Verduzco, 1992).

These data give us an idea of the variation in migratory profiles, even in states and regions of high migration, and also during different periods.

Therefore, if our interest lies in the remittances, although we can talk of overall quantities and average monthly or annual amounts, in fact they reach the communities of origin in very individualized ways for each one, depending on the migratory profiles at the time which sometimes or in some cases include many people but can then drop or even increase more. Similarly, in some periods people only go to the United States and in others that pattern coexists with internal migration also.

It therefore follows that we find very variable quantities in the different studies. For example, Orozco (*op. cit.*) made a calculation based on data from his three communities, and found that the income from remittances reached US$86,464, which represents 13.9% of the total income of the communities or the equivalent of US$371 a year per family. But he explains that this varies a great deal from community to community. Corralillos is where the most is received; there the annual income is US$548 per family, equivalent to 28.4% of the income, whereas in El Refugio it is only US$60 per family, equivalent to only 4.3% of the income. Obviously the differences between these quantities have much to do with each town's different migration patterns.

Massey and Parrado (1994) found similar behavior in their study of 22 communities in the states of Michoacán, Jalisco, Guanajuato and Nayarit, since the remittances calculated as a percentage of aggregate income obtained in Mexico varied from insignificant quantities to considerable amounts.

Similarly, in Gómez Farías, Michoacán, López, G. (*op. cit.*), calculated that remittances varied between US$80 and US$300 a month per family and that they could be equivalent to 19% of the income.

In the village of Tepusco (municipality of Villa Hidalgo, Jalisco), almost 100% of external family income comes from remittances, and these surpass the amount of public spending of the municipality (Arroyo, De León and Valenzuela, *1991*, p. 159). Moreover, in Colotlán, Jalisco, the same authors point out that remittances are the economic base of that microregion, since they also amount to much more than municipal spending. But by contrast, in the area of Ocotlán, also in Jalisco, which is an industrialized region, there is less migration and those who do migrate to the United States have the lowest levels of education, and hence the amount received there from remittances is relatively insignificant.

Owing to the above, and with good reason, they themselves affirm (1991: p. 244) that the average estimates of remittances have limitations in their interpretation because the majority of families in their study actually received small quantities, a few received larger amounts, and more than a third did not obtain anything. This study has the additional value of being representative of the "area of rejection" of Jalisco and included 69 communities.[10] Furthermore, J. Papail and J. Arroyo (1996) mention that between 27% and 32% of the migrants from the four medium-sized cities of Jalisco were unable to send money during their last migratory experience.[11]

In this regard, in the communities studied by Orozco (*op. cit.*), 13% of the migrants did not manage to return with savings from their last trip, while among the migrants from the city of Zamora (Verduzco, *op. cit.*), 27% were also unable to send money or bring it back with them, and of these, two-thirds never returned to the United States.

Actually this is a point that has not been commented on much, since it is more common to talk of the successes than the failures, but these data indicate a quarter and even a third of returning migrants who were unable to send or bring back money. It implies a difficult situation for many as a result of very resolute efforts.

In practice, the possibilities that individuals have of saving have to do with diverse factors. In addition to merely circumstantial aspects, it also depends on the situation of savings prior to the departure of each individual, since some travel with what they have saved in different ways in Mexico, while others have to go into debt and borrow and then have to pay back (in Mexico or in the United States), usually with high interests. Fonseca and Moreno (*op. cit.*) illustrate this point very well based on the accounts of various informants, although this is a recurrent theme in almost all the studies and very well known by researchers of the topic. Similarly, we know of the high costs of subsistence incurred by workers, particularly those who work isolated in the fields, as well as undocumented migrants who have to depend on intermediaries to obtain food, clothing and other types of goods in order not to place themselves at risk (Fonseca, O. and L. Moreno, *op. cit.*). Moreover, migrants have to face the costs of the journey itself, and especially payments to a "coyote" to cross the border, as well as bribes to Mexican officials upon their return to the country. This is also something well known from experiences of field work (see W. Cornelius, 1978; López, G., 1986; Massey, D. et al., 1987).

Ina Dinerman (1983) reported on the basis of the experiences of informants from Ihuatzio and Huecorio in Michoacán, that between US$250 and US$300 was spent on "coyotes" alone. At that time the money had to come from the activities of the community itself.

On occasions, the monetary success of the trip to the United States will depend partly on the economic situation in relation to the demand for workers in the period

of the journey, since, for example, J. Papail and J. Arroyo (*op. cit.*) found in their sample from medium-sized cities of Jalisco that 15% of returning migrants were unemployed immediately before coming back to Mexico. They also mention having found higher rates of unemployment among undocumented migrants that among documented ones. It is likely that these two findings, as it is a recent study, reflect to a certain extent the new situation that prevails in the United States labor market.

But the fact is, as can be seen from the above examples, that the income that finally reaches families is not always high; on the contrary, many expenditures of all types have to be made on the journeys there and back and during the stay, and it is common for workers to have to face variable periods without work (Mines, R. and S. Gabbard, 1993), and there are diverse losses connected with remittances. In fact this is a point on which more research is needed, since the cost of migration appears to be very high.

In another sense we know, for example, that in recent times wages have dropped for migrants and we are aware that in addition there is greater labor competition among Mexicans themselves; if this situation were to persist, faced with high subsistence costs, to what extent would future migrations be inhibited or change, and with them, the inflow of remittances? We believe it is possible to put forward the hypothesis of a relative saturation of the labor market, which together with the accompanying drop in wages could lead to a variable withdrawal of the supply.

Another important aspect that has not been dealt with in depth in research projects is a characteristics of remittances which, although known as a fact, has not been thought about sufficiently. Arroyo, De León and Valenzuela (*op. cit.*) point out that the remittances are: *unstable* and *cyclical* and therefore *insecure*.

These features have as much to do with the potential final benefits of remittances as with the series of family strategies that households should plan and execute.

It is true that these characteristics regarding the instability and insecurity of remittances occur, although we do not know exactly under what circumstances or to what extent.

In general terms the different studies show on the one hand, that there are workers who, probably because of past experiences, as well as because of their contacts through the networks and the more stable type of work they will carry out, manage to engage quickly and without obstacles in some form of employment. In such cases, the money they manage to save after deducting their expenses could be channeled in a more stable manner to their families. On the other hand, there are also the data of workers who did not manage to bring back or send any savings to their families, as well as information showing that the expenses incurred

by migrants in order to cross over to the other side and then maintain themselves, especially if they are undocumented, are high and perhaps higher than for those who are residents or those who already have papers. Furthermore, we also know that there are activities, particularly agricultural ones, that do not make it possible to have work continuously throughout the year. In fact this is a point on which further research should be carried out in order to grasp the nuances of the costs in this type of labor experience which is determined by the types of work demanded, and by the clandestine forms of arrival and labor integration which are so specific.

Remittances: Dependence or Development?

Another common concern with the subject of remittances has to do with their use. Therefore, in general the authors have made efforts to find out not only how much reaches families, but also how it is used and what effects it promotes.

In general, but especially at the state and local levels, the generally shared premise is that migrants' contributions to their regions of origin help to improve living conditions in said regions, even when the literature also tells of some counterproductive effects in the form of conspicuous consumption, inflation and effects of displays of consumption (see W. Cornelius, 1990, p. 98-9).

First of all, it has been found by researchers that the remittances are used mainly for consumption, both for subsistence and for the acquisition of diverse goods. Secondly, they are used to enlarge and embellish houses, as well as to improve them with electricity, water and drainage services. Different debts incurred are also paid for and the "northern" money is used to contribute to community fiestas or to give parties themselves, as well as to support communities' urban infrastructure works.

In general terms, it tends to be evident that communities with more migration look different, as described, for example, by Luis Rionda for Copándaro, Michoacán (1986), or by Gustavo López for Gómez Farías (*op. cit.*). It is common for there to be better houses in those places, as well as good urban services, or at least better than in other neighboring communities.

However, at times a certain frustration can be perceived in the researcher at not finding more productive investments in the communities (W. Cornelius, 1976 and 1990), as it would be wished that by taking advantage of migration, the people of the villages could make progress. There is also the hypothesis that migration could be an endless chain and only useful for consumption (Russell, 1992).

The High Cost of the Migratory Experience

As was mentioned earlier, it is more or less clear that there are some costs that do not allow better tapping of migrants' efforts. This is a point that for the time being darkens the outlook for migration. For example, in the surveys carried out by Papail and Arroyo it was seen that in the four medium-sized cities of Jalisco, the average income from migration was equivalent, in 1993, to the average income in those cities. In reading that information we would say that the comparison most commonly made with the wage gap between the two countries, which is normally estimated at 1 to 10, is actually unreal because the net amount that would be earned with the effort of migration would not exceed what is finally obtained here. Nevertheless, if we consider that in those same cities only 40% of the economically active population earns on average that income, this would give us a more approximate dimension of the real importance of remittances for those places, especially for those who emigrate from there (op. cit., p. 119). But from another point of view, that fact shows that the real possibilities for savings or productive investment are rather limited.

At any rate, having made these considerations, a review of the literature shows us contrasting situations. But first it is necessary to make an observation. With the exception of the research carried out by Papail and Arroyo (1996), Massey, D. et al. (1987), González de la Rocha and A. Escobar (1990), Verduzco (1992) and Durand (1994), all the projects that have some locality as a unit of analysis center on the rural sector and are oriented, when they do so, to a study of agricultural activities. Actually this is logical since, as we have seen, these migrations come mainly from the rural sector. Nevertheless, a limitation tends to persist in the works of researchers, and this is that owing to the complexities of the analysis, the community is viewed as a sort of special world (which it is for the researcher), where what counts is the community and its immediate surroundings and migration to the United States. At times the studies fail to observe that Mexican rural communities have been following the tenor of the changes in the country. These changes have signified, among other things, a sharp drop in the agricultural work force which has gone hand in hand with a drop in the economic importance of agricultural activity in comparison with the rest of economic activities. In an important sense for migrations it has implied that, since the late 1960s, the country's "rural" population, particularly *campesinos*, can no longer survive without the support of their own people working in Mexican cities or in the United States (Arizpe, 1980; Verduzco 1985; Arias 1992). In fact, if we analyze the extensive literature on regional development and urbanization in the country, we find that temporary and definitive migration to Mexican cities has predominated over migrations of diverse types to the United States, but the fact is that rural inhabitants have not lived from agriculture alone for several decades.

The above digression makes sense inasmuch as it has been common for some researchers to want to see productive investments in rural settings which no longer have the capacity for investments of that type.

But having stated these considerations, we can mention two types of communities in general that appear in the literature. In some there seem to be no productive changes, or if there are, they are perceived as being of minor local or regional importance and migration appears rather as a process that establishes a dependence on remittances and the exterior. This could be the case with places such as Huecorio (Dinerman, 1982), Jaripo (Fonseca and Moreno, 1984), Gómez Farías (López, 1986), Chamitlán (Massey et al., 1987) Las Animas (Goldring, 1990), Corralillos (Orozco, 1992), Tepusco and Colotlán (Arroyo, De León and Valenzuela, 1991).

On the other hand there are communities where remittances appear to have supported processes of change, or where because processes of productive change have taken place, remittances were viable as investments. Such a case is reported by Acheson (1974) in Cuanajo, Michoacán, where the *braceros'* remittances helped to start furniture workshops. In Ihuatzio, also in Michoacán, Dinerman (*op. cit.*) describes how with the support of remittances, crafts have provided a new alternative for some of the inhabitants, an activity that did not exist a few years earlier. In Chilchota, Michoacán, something similar occurred with the different crafts that emerged there (Ramírez, Luis, 1988).

In Copándaro, Michoacán, Rionda (1986) recounts how remittances have supported agricultural mechanization, as well as the development of lentil cultivation, of which Michoacán has now become the country's main producer. Furthermore, activities of breeding and fattening cattle and hogs have been developed. Nevertheless, although there have been a number of changes in the town and some groups that used to migrate no longer do so, there has now been an easement of migration by other sectors of the population.

In Jalisco, moreover, Orozco (*op. cit.*) reports that in the town of Los Dolores the productive changes and the improvement of living standards have been very noticeable as compared with the other two communities he studied. In Los Dolores remittances contributed to the changes and where in the past there was a pattern of intense migration, now there is very little.

Arroyo, De León and Valenzuela (*op. cit.*) point out in their study of Jalisco's rural "area of rejection" that of the different areas they studied, that of Tepatitlán is where there is the most productive investment from remittances. This goes particularly to agriculture and other types of business.

In another study, but of the urban sector, Papail and Arroyo (*op. cit.*) also report that the region of Tepatitlán, Jalisco, is where in comparative terms there has been the greatest productive investment from migration. There the remittances have been used to support poultry farming; but it should be noted that it is estimated

that that city and its area of influence produce around 30% of the country's eggs and chicken.

In the city of Zamora, Michoacán, which is a subregional city in the northwest part of the state, Verduzco (1992) studied the changes in the region's rural and urban sectors, as well as the characteristics of the diverse migratory flows, including international ones. The study suggests that owing to the intense agricultural development and the promotion of urban activities, migrations to the United States had probably diminished over time. It was also suggested that the reduced migrant sector of the present time was different from that of other periods.

Likewise, Papail and Arroyo suggest something similar for the medium-sized cities of Jalisco studied by them.

But apart from these instances that refer to diverse achievements of certain importance for communities and sometimes for regions, there are other accomplishments, perhaps more limited, but no less important.[12]

In the studies of Arandas (Taylor, Paul, 1932), Jaripo, Gómez Farías, Chavinda (Alarcón, R. 1984), Huecorio (Belshaw, 1967), Alvaro Obregón (Trigueros, 1994), Cherán (Beals, 1946) and a few others, it appears very clearly that during different periods, but especially in the 1940s, when it was evident that there were *ejido* lands together with a modernizing impetus but without capital or machinery, migrations, through the *bracero* contract, helped to support those processes in various ways. In this regard let us recall, as is stated repeatedly in the literature, that migration takes place with very specific objectives, and this was indeed the case during those years, since there were lands and conditions to cultivate them, but official bank credits did not yet exist, as was to happen later.

From another perspective with comparative purposes, recent works by E. Taylor (1996) and Yúnez (1997), based on building the social accountability matrixes of various communities, offer preliminary conclusions, but no less convincing, that emphasize the need to distinguish the effects, taking into account the differences between localities. For example, the micro-multisectoral study in rural localities with different characteristics, commissioned from Antonio Yúnez (1997), establishes the differentiated nature of the impacts of foreign-currency inflows, whether from remittances or from exports, depending on the importance of the foreign currency in the specific locality vis-a-vis other resources.[13] The extreme cases in his study illustrate the point: Napizaro (Mich.) is the locality that is most dependent, in relative terms, on remittances and therefore the one that maximizes the multiplying effects of a change in the inflow of foreign exchange (whether because of devaluation or increased hiring),[14] while Concordia (Coahuila) has a more balanced economy that depends to a lesser extent on remittances and that gathers more limited multiplying effects of a change in foreign currency (see tables 4a and 4b in Yúnez 1997). The implementation of this methodology presupposes a

good dose of technical sophistication together with high costs in gathering the information from each community, but it is undoubtedly a promising alternative in the search for more precise conclusions.

In general terms, these diverse effects and changes at the community level are also in harmony with findings reported in similar situations, together with migration, in other parts of the world (Taylor et al., 1995). The interpretation of many of these cases coincides with that of other authors who, for other national contexts view remittances as a vehicle for furthering the development of areas of migratory expulsion, as long as the channeling of the remittances goes hand in hand with other conditions. Unless there is better research on causality, as pointed out in those studies, a generally accepted condition is being able to concentrate other private and public resources, notably for infrastructure, in those same areas, otherwise the effects of the remittances will be used on basic consumption with fleeting distribution or multipliers (Massey, Arango, Hugo, Kouaouci, Pellegrino and Taylor, 1993; Díaz-Briquets, 1991).

The result of these proposals contains clear implications of trade-off for the public policy of both countries: it may be convenient for the United States for a greater intensity of remittances to be concentrated in few areas in Mexico in order to ensure the multiplying effects that would reduce dependence on said remittances in the future; for Mexico it involves concentrating in the same regions of origin, and mainly in those with the greatest development potential, to the detriment of other regions that are also poor, a greater proportion of the effort for investment in infrastructure.[15]

Migrations and Some Economic Improvements

Along with the data and interpretations on the use of remittances, researchers concur unanimously in reporting that migratory workers use part of their savings from working in the United States to improve their homes, whether by decorating them, extending them or introducing basic services such as electricity, water and drainage. Similarly, it is common to find that localities with migrants benefit from their contributions by receiving monetary support that helps them to improve diverse services, whether urban infrastructure, health, religious, educational or entertainment services. In towns with migrants it is common to find acknowledgments from the residents to their fellow townsmen for having helped them build a school or health clinic, or to introduce drinking water or build or improve the church, etc.

It also has been common for researchers to report a certain channeling of savings into productive activities, especially agricultural ones, mainly in aspects

related to the acquisition of agricultural machinery or implements, as well as other types of improvements or small technical innovations, etc.

Below we will try to analyze to what extent the situation as regards some of these services or technological innovations characterize the municipalities with the greatest migratory *intensity*, at least in the states that in relative terms have the greatest presence of the phenomenon of migration.

These states are the following: Chihuahua, Durango, San Luis Potosí, Zacatecas, Guanajuato, Jalisco, Michoacán, Guerrero and Oaxaca.

We proceeded to differentiate the municipalities according to the category of "migratory activity," into "low," "medium," "high," and "nonexistent" in the way this is presented initially in the first pages of this chapter. In accordance with these categories we applied the analysis of variance to ascertain whether the null hypothesis that there would be no differences between the four groups could or could not be rejected.

Overall for the series of municipalities in the 9 states, the following variables were statistically significant:

1) Percentage of housing with electric power;
2) Percentage of housing with piped water;
3) Percentage of housing with 2 to 5 rooms;
4) Percentage of livestock production units that use some kind of technology;
5) Percentage of rural production units that use some kind of technology.

Furthermore, a number of differences appeared at the level of the diverse states.

In Chihuahua, for instance, the percentage of housing with drainage and the percentage of housing with 2 to 4 bedrooms (size) were significant.

In Guanajuato, however, only the use of technology in agricultural units was significant.

In Guerrero, the variables concerned with housing (drainage, water and number of rooms and bedrooms), and the use of livestock technology were significant.

In Jalisco, water in housing units and the variables referring to the use of tractors and livestock technology appeared as significant.

In Michoacán the variables concerning housing (water, drainage, electricity and size), as well as those relative to the use of tractors and livestock technology were significant.

In Oaxaca, the same variables as those for Michoacán were significant.

In San Luis Potosí, only those concerning the size of housing units were significant.

Finally, in Zacatecas, the water in housing units, the use of tractors and the use of agricultural and livestock technology were significant.

We thus have an initial statistical confirmation of the possible impact of migration on the states with the highest level of migratory activity in the country. And furthermore, as we have seen, there are important variations between the different states, a situation that suggests that the purpose of migrations can also vary a great deal from one state to another, as was pointed out in the first few pages.

These are important clues that would be useful to take up in future research in order to avoid generalizations on the variable conditions of municipalities of origin, as well as of the impacts.

Another way, although limited, of observing the possible impact is to compare the situation of municipalities in each state in accordance with a certain series of characteristics, trying to differentiate between municipalities with *intense* migration and those with low migratory activity. Although this is a more descriptive form, it may nevertheless be illustrative and therefore, by way of example we will present only the case of the state of Michoacán, since it is the only one that fulfills various conditions that make it possible to make this observation by means of this technique.[16]

For housing conditions, a few "strata" have been made with series of municipalities that present some similar characteristics within each stratum, but that show differences between the "strata." It is therefore a group of municipalities within each state according to their similarities and differences with regard to a set of variables that have to do with housing conditions.[17] These "strata" were ranked from lowest to highest in order to be able to observe which municipalities make up each "stratum."

In the lowest "stratum" are the municipalities with the worst housing conditions, and in the highest stratum those that have the best.

In Michoacán, for example, of the 27 municipalities with *intense* migratory activity, 23 (85%) are in the top 2 strata of a total of 7 strata, despite the fact that, as will be recalled from earlier pages, the municipalities with *intense* migration are rural. Of all the municipalities with the best housing conditions in the state (56 municipalities), 41% are municipalities with *intense* migratory activity. (See map attached at the end and observe how almost all the municipalities in strata 6 and 7 are in the northwestern section of the state. That is the section of the state with the most migratory activity.)

In summary, the above information confirms, through the use of statistical techniques, some possible impacts of remittances in specific conditions that have to do with housing and agricultural productive activities. And, as was mentioned earlier, these findings are in general harmony with what has repeatedly been reported in community studies over time.

Migrations and the Selectivity of Migrants

The topic of the selectivity of migration has had special importance in studies on migration in general, because it allows us to situate the migrant population in comparison with the nonmigrant population.

Until a few years ago the shared common knowledge was that those who migrated to the United States were largely *campesinos* with low economic and educational levels, but higher than their nonmigrant fellow countrymen. This is a fact that was corroborated by different researchers over the years and also confirmed by the first major national survey on migration organized by CENIET in the late 1970s (Zazueta, César, 1982).

We must accept, however, that this is a topic in which more research is also needed, since what is known is rather general and not very detailed, and the information available is really limited. It would be of particular interest to know more about conditions of selectivity in more recent periods.

Massey et al. (1987) observed in four communities of Michoacán and Jalisco that migrants to the United States did indeed have more schooling than nonmigrants, but they saw that they had less than migrants to other parts of Mexico. Likewise they saw that more rural workers went "North" and that those who were engaged in nonrural activities tended more to go to Mexican cities.

The works of Arroyo, De León and Valenzuela point out that the selectivity of migrants varies in different areas. In Ocotlán, for instance, which is an industrial area, those who have less schooling cannot take part in those jobs and opt for working in the United States. On the other hand in Colotlán the well-known pattern of more schooling than nonmigrants is followed.

In Zamora (Verduzco, 1992), migrants are a negatively selected group compared to those who do not migrate, although they have more schooling than the rural migrants from the same region. Moreover, the "recurrent" migrants have even greater negative selectivity.

Papail and Arroyo (*op. cit.* p. 63) found in their sample of the four medium-sized cities of Jalisco that both current migrants and male ex-migrants had a slightly lower level of schooling than nonmigrants in all age groups.

In the data from the survey on migration in Zacatecas (1991), we see that the positive selectivity of migrants in terms of both schooling and occupation predominates. Let us recall that in that state migration from rural municipalities predominates and that *intense* migration is also important.

Finally, the Survey on Migration to the Northern Border (EMIF) points out that the population between 15 and 44 years of age has a lower level of schooling than the population of those same ages resident in Mexico (Corona, 1996).

Although more research is needed on such an important and delicate topic, there is room for the hypothesis that probably a significant portion of current migratory flows is composed of persons with a low level of schooling and even negatively selective in comparison with nonmigrants. It is also possible that the findings in the United States with regard to this point are consistent with what is observed from the Mexican side. If this tendency were true, it would be telling us of a very specific labor demand at present.

The Demographic Impact of Outmigration

It is estimated that between 3.5 million and 4.0 million Mexicans became United States residents between 1980 and 1995. The majority of that population (85%) is aged between 15 and 64 and only about 4% is older than 65.[18] Therefore a majority of that population is of working age and is penetrating the U.S. labor market.

Although overall the loss of this population may not be significant for Mexico (it reaches 4.2%), it accounts for around 10% of the population in the states with the highest levels of emigration. In this regard it should not be forgotten that the majority of this loss includes persons of working age, and therefore from that perspective the exodus of population is bound to have more of an impact on those places, particularly as regards the effects that may be expected in the future. Population projections for the year 2010 in those states indicate a net reduction in the population growth rate of between 0.8% and 1.0% a year. In those states the loss of population due to earlier emigrations, coupled with present ones, could reduce the expected population increase by up to 46% (Gómez de León and Tuirán, 1997).

The Costs of Migration

Despite the uncertainty in the tendencies of selectivity of migrants, it is a fact that migration involves considerable costs for Mexico, although rarely has an attempt been made to measure them. An estimate of the costs of migration may be attempted by addressing the components of investment in human capital and relative quality of migrants.

We consider three types of costs associated with migration from Mexico: labor opportunity costs; costs for selectivity and family and community costs. Thus far these have received very little or no attention at all in the literature on migrations, since, for example, labor opportunity costs have been estimated to be small by assuming an excess of redundant labor in the country of origin. For Mexico this assumption is questionable because of the condition of selectivity of its migrants, which implies considerable costs.

1) Labor Opportunity Costs: Costs of Education, Health and Social Infrastructure.

These are the costs incurred throughout the life of individuals to achieve an economically active person in good conditions of health and education.

The cost for Mexico is the opportunity cost represented by having invested in preparing that person and not retaining the added value of all his activity for the benefit of the country. The net returns of that person for the country are remittances or savings, which hardly exceed 10% of the wages earned in the United States. That wage is equivalent to the added value they contribute to the other economy.

There are relative costs or returns. By return we understand the quotient between what is obtained as a wage or added value and what is invested or spent in exchange for that product. For Mexico the return is small if we consider the quotient between the amount saved from the wage paid to migrants and the costs of education, health, etc. incurred by Mexico. The return on migrants is only in relation to the net amount in remittances or savings, as approximately 90% of what they receive in the United States is consumed in that country. In this regard, it is incorrect to associate the total U.S. wage with Mexican earnings. The literature points out that the net amount of remittances is, on average, equivalent to the amount provided by the average earnings in urban localities of origin in Jalisco (Papail and Arroyo, 1996). The approximation of costs incurred by Mexico is very high. This would include, for the education of Mexican workers resident in the United States alone, between US$40 and 50 billion.[19]

From the viewpoint of the country of destination, the return on what is paid to Mexican labor is very high, since there has been no need to incur costs of education, health and social infrastructure. While that denominator is small and sometimes close to zero for the host nation, we are talking about very high returns.

2) Comparative Costs for Migrants' Selectivity

Two stages or periods must be recognized in appreciating selectivity. The first is better known, when the population that migrates is compared with the population that remains, using numerical indicators (usually years of schooling). In this comparison the result tends to be positive selectivity in rural migration but negative in more recent migration of urban origin. The second stage in perceiving selectivity is by controlling the comparison for groups with the same schooling. In this case the hypothesis that still dominates is positive selectivity, reflecting enterprising qualities and the ability to face risks on the part of migrants. It is common for the young people with the most initiative to leave, with the result that communities lose their current and potential leaders, and their capacity for interaction with the exterior is also weakened.

3) Family and Community Costs

Migration is accompanied by significant changes in forms of family organization, such as a necessary additional effort by families to facilitate the migration of one or several of their members. Similarly, in the communities with the greatest migration, major changes occur in those communities' social and political organization (Zendejas, 1995), which frequently make themselves felt in diverse negative situations for their inhabitants. It is also common for migration to be accompanied by serious problems of family disintegration, as well as by the appearance of different psychological and social problems that were previously nonexistent in the communities of origin.

Although such social costs are difficult to estimate accurately, observers have realized their great importance in the communities of origin and it would be necessary to carry out systematic studies so as to be able also to plan the establishment of measures of support that could lessen their negative effects.

Migrations and the Social Organization of Communities

Along with the existence of intense migratory flows to the United States, some researchers, mainly anthropologists, have described types of behavior and specific situations that have influenced the life of localities.

Reichert, J. (1982) called it the "migration syndrome" and then Alarcón, R. (1988), broadening the view of the phenomenon, called it "northernization." In short, it is a question of the process that occurs particularly in communities with intense migrations and where, owing to the effect of the large volume of people involved in migration, important changes take place not only on a family but also on a community scale. It implies changes in the family, in labor and economic organization, in perceptions and culture, and in community and political participation.

Dinerman (1983) carefully describes how within families, the roles and economic functions of the different members have to be reassigned in accordance with migration and cultivation cycles, faced with the real possibilities and the expectations of migration. Besides, the relations of reciprocity that were previously frequent, especially in indigenous communities, are upset by the need to use wage-earning workers owing to the absence of male community members.

Recently, important changes have taken place with the increased presence of women migrants, as pointed out by Donato (1996).

At the family level, the departure of the husband and father also leads to friction and problems in the family that are not always easy to put right (Orozco, *op. cit.*).

Furthermore, Bohem, B. (1985) also mentions how because of migration, reciprocal commitments are established between the migrant and the extended family,

as well as between families when there are activities that should be covered in the absence of the migrants. Over the years these small influences end up by changing important aspects of communities' social organization.

Alarcón, R. (*op. cit.*) also mentions how because of the fact that the young people with the most initiative leave, the current and potential leaders in communities are lost. This leads to a weakening of communities in their relations with the exterior, especially with government agencies in negotiations for services. Community participation is also weakened.

López (1986) and Alarcón (1988) mention how because some communities are closely linked to international migration processes, there are perceptions and expectations of another kind that have little to do with local living conditions in the communities.

In summary, this type of migrations, because of specific characteristics as regards the prolonged absence of one or various members of families, especially when in addition there are many families in a community in this situation, produce problems and frictions of different kinds which, although little known to us, constitute a significant cost for families that find themselves in those circumstances.

It is a question, on the one hand, of emotional costs that weaken the different members of migrants' families, and on the other, of social and economic costs because of the need to cover adequately the functions that the migrant leaves vacant both in his own family and in the community.

Finally, this study has shown the limited knowledge we still have as regards some of the important impacts of migration: in the United States there are few studies on the benefits that Mexican labor migration contributes to the country, particularly in the sphere of economic production, whereas in Mexico, little is known about the multiplying effects of migration in terms of development. As regards costs, little is known in Mexico, especially in the sphere of social problems in the communities of origin. Furthermore, there is still the need for an overall view of the two countries in order to understand the logic of the social costs that migration implies for the United States, together with another on the cost for Mexico of preparing a labor force whose returns are in the United States.

Notes

1. We are grateful for the collaboration of Antonio Yúnez, Fernando Lozano, Christian D. Muñoz, Luz Consuelo Saldaña, Virginia Levín and Fernando Cortés in different activities that made the preparation of this paper possible.

2. Hall and Coerver (1990) notice that according to the U.S. Department of Labor in Washington between 1910 to 1920, only about 200,000 Mexicans intended to stay in the U.S. as legal migrants; the rest were considered as "temporary visitors" due both to the internal war in Mexico and to labor demands in the U.S.

3. The demographic loss to Mexico due to migration in recent years, from 1981-95, of 4.2% of total population, is now a little larger than what was in the 1920s.

4. "Migratory activity" is estimated from the data on the number of persons who returned to the households of those interviewed between 1987 and 1992 in the National Survey on Population Dynamics (ENADID), the sample size being 800,000 cases. Based on that information, Rodolfo Corona estimated the proportion of those persons in comparison with the municipal EAP (Economically Active Population), and it has been on the basis of that basic calculation that we have created three categories of "migratory activity": "low" (from 0.1% to 6.9% of the EAP); "medium" (from 7.0% to 24.9% of the EAP) and "high" (from 25% to 100% of the EAP). We believe that levels between 0.1 and 1.0 may be considered extremely low.

5. In the 1960s it was said that the second city with the most Yucatecans was Los Angeles, California. However, it would seem that those flows have diminished over the last few decades, probably as a result of the major economic dynamism experienced in the Yucatán Peninsula because of petroleum in Campeche, livestock-raising, especially in Quintana Roo, and tourism in Cancún and the Maya areas. The positive migratory net balances of the last few years indicate that that region has gone from being one of expulsion to become an area of attraction of population.

6. It should be recalled that Oaxacans participate in various important migratory circuits within the country, among the most prominent being agricultural seasonal day laborers. There are also significant contingents of Oaxacans in the Federal District, Tijuana, the San Quintín Valley, Baja California, Sinaloa, and in the oil-producing areas of Veracruz and Campeche.

7. Note that in different information sources, localities of more than 15,000 inhabitants are commonly established as being of "urban" category, and therefore perhaps, in order to avoid confusion in the scales of what is urban, it would be preferable to talk of the number of inhabitants of those places, since ultimately what we want is to have an approximate indicator of levels of socioeconomic differentiation in those places.

8. In four of these municipalities, studies have been carried out on one of their localities: in the community called La Yerbabuena in the municipality of Tlazazalca (Reichert, 1979); in Gómez Farías, in that of Tangancícuaro (López, Gustavo, 1986 and Goldring, 1990); in Chamitlán, the chief town of the municipality (Massey, D. et al., 1991); in "Jaripo" in the municipality of Villamar (Fonseca, O. and Lilia Moreno, 1984).

9. It should be recalled that the state of Oaxaca has 570 municipalities.

10. In fact this is an approximation, since although there is migration from those places, we do not know how many migrants come from the urban localities that may exist in the municipality.

11. This was a very extensive study which was representative of a "rural area of high rejection" of Jalisco. It comprised 26 municipalities, 69 localities, 576 families and 3,739 persons.

12. This study was based on statistically representative samples for the four medium-sized cities of Jalisco.

13. The perceptions of different authors tend to be contrasting. For some, the benefits stemming from the establishment of new small businesses are considerable. See, for example, the summary review of studies that record the capitalization of remittances into own businesses, in Taylor et al., 1996, p.402. Others do not consider them significant. An account

of the ambivalences may be seen in Cornelius 1990, p. 96-7. As obvious as it may seem, the opinion will depend largely on the moment or phase in the development of the community in which the observation is made.

14. These differences coincide with what has been reported by other authors on similar topics. Durand and Massey, for example, find major differences between communities as regards the percentages reached by productive expenditure as the purpose of migradollars (reported in Taylor et al., 1996, p. 402).

15. Although, as can clearly be seen in the work of Lozano (1997), two-thirds of remittances have come from Mexicans resident in the U.S., which leads one to suppose, given the trends observed, that these will gradually diminish in the future. This drop at the community level is also reported by Zendejas (1995) for the town of Erícuaro, Michoacán.

16. The dilemma is well expressed by Martin: "The neglect strategy makes emigration areas even more dependent on an external labor market (Mexico's central highlands); but the subsidize-the-remittances strategy increases regional inequalities within emigration nations." (ibid., p. 658.) Certain isolated evidence shows the federal government's indifference towards states with migration. For Zacatecas, for example, it is estimated that federal outlays are equivalent to less than one-third of the inflows from remittances (see Tamayo and Lozano, 1990, p. 20)

17. In addition to the fact that Michoacán is a state with a considerable proportion of municipalities with *intense* "migratory activity," the use of the technique of analysis of variance already confirmed also that in that state, various of the variables referring to housing were significant.

18. These variables were: Proportion of housing units with drainage; with piped water; with electricity; with one room; number of occupants per room; and proportion of housing units that use firewood or coal for cooking.

19. Data from the Current Population Survey, 1995.

20. But we must be cautious with these numbers since there is a great complexity in the estimation of these numbers. The amount provided in the text is a preliminary estimation of these type of costs.

Responses to Migration Issues

*Sidney Weintraub, Francisco Alba, Rafael Fernández de Castro & Manuel García y Griego**

Introduction

This chapter provides detailed background to the material on responses to migration issues contained in the report *Binational Study: Migration between Mexico and the United States.*

The time frame of this discussion of responses to migration issues begins essentially with the termination of the Bracero Program in 1964 and goes to the present. The pre-*bracero* period obviously had considerable influence in shaping Mexican and U.S. responses to human movements, but brevity requires some point of departure. Most emphasis in this discussion will be on more recent responses.

The organization of what follows is divided into nine section. See also Volume 3, pages 1215 to 1250, for additional material, including four brief case studies illustrating the nature of the analytical model. These studies deal with the Bracero Program; the migration ripple effects of the 1982 economic crisis in Mexico; the effort to stimulate an economic-development response alongside the 1986 IRCA legislation; and the Mexican reaction to the incidents in Riverside, California, in 1996.

The nine sections in the body of this discussion are the following:

1. *Analytical model*. This is designed to set the framework from which decisions are made to respond to what are seen as migration-engendered problems.

2. *Differing perspectives*. It is not necessary to elaborate on why the authorities and public in Mexico, the sending country, view migration issues differently from these groups in the United States, which receives the immigrants. Yet is important to keep these differences in mind when seeking the kind of cooperation that this bilateral study implies. There is a predilection for Mexicans to see migration, undocumented or otherwise, as a relatively benign, really unavoidable, development given the situation in that country, and for Americans to be less sanguine about immigration in general and negative about illegal immigration. There really is no completely consensual attitude.

3. *Objectives of the two countries*. This section flows logically from the previous comment on the different perspectives of the sending and receiving countries.

4. *Societal attitudes*. This section will draw heavily on polls and focus groups. It also will examine the forces shaping these attitudes.

5. *Legislative and judicial responses*. The main U.S. responses take legislative and judicial form. They do to some extent in Mexico as well, but also are reflected in official statements and in reactions to U.S. responses.

6. *Other actions*. These relate either to non-legislative and non-judicial responses and to actions to enforce laws and judicial decisions.

7. *Responses and reactions thereto*. When one side acts, the other may respond. The reaction may deplore the initial response, or it can reinforce its intent. The typical sequence in the past was a one-sided response to a perceived problem, reaction to that response by the other side, and then possibly a counter-reaction by the original respondent. The one-sided nature of initial responses is increasingly giving way to dialogue before action is taken. This study, for example, grows out of a Mexican proposal for a binational examination of the migration issue and a positive response by the United States.

8. *The changing relationship.* U.S.-Mexico relations have been altered by the existence of NAFTA and the cooperation this demands on trade, investment, financial, and other economic issues. NAFTA has spawned considerable institutionalization of the economic relationship and the contacts being developed spill over to the migration field. NAFTA does not provide complete insulation against bilateral conflict, as the March 1997 U.S. debate over decertification of Mexico for insufficient cooperation to reduce drug trafficking illustrated. Mexico was eventually certified.

9. *Conclusions*. The basis for these are set in the main body of the discussion. The conclusions can also serve as the starting point for policy discussion.

The Analytical Model

The normal pattern is that pressure calling for a response to a perceived migration problem builds up in the United States, the receiving country in this bilateral relationship. This means that the United States generally takes the initiative. Mexican authorities and society at large may deplore the conditions that push migrants out of the country, but the corrective in the Mexican system cannot be to act independently to keep people from leaving. The solution to the emigration pressure is seen in Mexico as being long term in nature, to alter the national economy and societal conditions enough so that more Mexicans will stay at home voluntarily. This means that most Mexican responses will be reactive. As in many other facets of the bilateral relationship, there is an asymmetry in responses to migration matters.

The pressure that prompts a response can originate in either country, or in both simultaneously. The most usual progression is for a series of developments to build up over time and be brought to a head by a single event or series of events. The passage of Proposition 187 in California in November 1994 can be seen as a response to what was believed to be rising illegal immigration combined with an economic downturn in the state. This legislation, in turn, triggered an instinctive anti-California (anti-U.S.) reaction in Mexico. The high-speed chase and televised beating of illegal immigrants by Riverside County police triggered a strong outburst in Mexico, but this had been preceded by long-standing Mexican concern over the violation of the rights of its nationals in the United States.

One can cite any number of situations that led to significant responses. The shortage of manpower during World War II stimulated the Bracero Program. The sense that these Mexican workers were adversely affecting wages of a sensitive U.S. group of workers led to the termination of the program. IRCA came to fruition in the United States from a process of long study, including the use of commissions established either by the executive or the Congress; the first of these commissions was established earlier when the U.S. economy was performing poorly.

Recession and economic depression in the United States is often the underlying stimulus for a response of immigrant exclusion. This was true during the Great Depression, just as it was in California in the first half of the 1990s. An economic crisis in Mexico in 1982 added to the U.S. economic pressure leading to the IRCA legislation.

Budgetary concerns, both state and national, have been a key stimulant of recent U.S. responses to perceived immigration pressures. Proposition 187 was preceded by studies depicting (and often exaggerating) the high cost of providing public services to aliens illegally in California. The 1996 immigration legislation was substantially influenced by budgetary considerations. Those provisions of the welfare-reform legislation of 1996 restricting benefits to legal immigrants were prompted largely by federal budgetary considerations.

The model set forth here argues that significant responses in the migration field are not usually generated solely by immigration pressures, but only when these come in combination with other events and developments. If the combination is not present, the immigration pressures by themselves are unlikely to lead to meaningful responses. The U.S. Congress did not act to provide significant additional funding for the Border Patrol until the last few years, when the movement of undocumented workers over the border combined with the declining California economy and the increasing attention to the costs of providing services to these immigrants at a time of constrained budgets.

The most important U.S. responses have a protracted gestation period, years in the case of IRCA, decades really for providing adequate funding for the Immigration and Naturalization Service. Debate on immigration responses is usually emotional because immigration is central to the way Americans define themselves. Debate is generally fierce because there are many competing interests. These include important employers of immigrants, including those who are present illegally, who seek to limit effective control mechanisms or, failing this, to extract some exceptions for their needs. The Special Agricultural Worker provisions of IRCA and the ability to hire foreign mathematics professors and skilled computer technicians are examples of the latter. The "half-open door" so familiar to students of U.S. immigration practice, that immigration legislation either is riddled with loopholes or inadequately enforced, is the result of these differing views.[1]

Because of this internal conflict, immigration legislation contains many compromises. This is self-evident, but taken one step further, it means that some issues are resolved, while others are left pending for future debates. The ink is barely dry on the 1996 immigration bill, and debate has already begun on the desirability of new legislation to reduce the number of legal immigrants permitted to enter the United States. The fact that each bill is the result of compromises is hardly an earth-shaking observation, but what seems to be happening is that immigration debates are coming with greater frequency. It took 13 years for the McCarran-Walter Act to be amended substantially by the Immigration Act of 1965, 11 years for the Eilberg bill to extend country ceilings to the Western Hemisphere in 1976, four years to adopt the 1980 Refugee Act, and another six years until IRCA was passed in 1986. Then, more recently, the United States added the Immigration Act of 1990, then the most recent legislation in 1996, and a new debate is taking place for possible legislation on legal immigration. Since 1980, the United States has enacted significant new immigration legislation every few years, on average.

One final point needs to be added to this analytical model, namely, the extent to which Mexican interests are factored into the shaping of U.S. policy. In the past, this took place less through the openly stated opinions of the Mexican authorities because these opinions were rarely given. The Mexican interest was included

primarily through alliances, tacit or explicit, with U.S. interest groups seeking the same outcomes as the Mexican authorities. For example, the legalization provisions of IRCA favored Mexicans based largely on domestic U.S. concerns working in tandem with Mexican hopes.

In more recent years, roughly the last 10, discussion between Mexican and U.S. authorities on immigration matters has become quite common. Mexican viewpoints, to some extent, are thus factored directly into U.S. policy, such as commitments to protect the rights of Mexican nationals. Mexico, however, has not reached the point where it lobbies directly with the U.S. Congress on immigration legislation.

The steps in the analytical model, to recapitulate, are roughly the following:

- An underlying context conducive to some U.S. immigration response, one usually rooted in the U.S. economic situation;
- A triggering event or series of events, either in the United States or in Mexico;
- A period of U.S. debate and political compromise that resolves some differences but leaves other issues on the table;
- A Mexican reaction to the U.S. action, and perhaps a U.S. counter-reaction;
- A new context for the next series of triggering events;
- And a speeding up of the process of additional immigration reforms.

Differing Perspectives

The perspectives of a country sending migrants necessarily differ from those of the country receiving immigrants. The normal power relationship in this kind of twosome favors the receiving country which, in principle, has the ability to decide what immigrants it will accept and under what conditions. In reality, the U.S.-Mexico migration relationship is more complex than this simple model. The border between the two countries is extensive and porous, notwithstanding the increased resources now at the disposal of the U.S. Border Patrol. This gives individual Mexicans considerable leeway to affect migration decisions and outcomes.

During most of the past two decades, the Mexican authorities remained aloof from this decision-making contest. This is now undergoing a subtle transformation; the Mexican government is prepared to consult with U.S. authorities on migration issues. Nevertheless, the basic situation is largely unchanged in that the contest is between migrants themselves and U.S. authorities. In the past, the U.S. authorities refrained from entering this contest fully and a Swiss-cheese border

full of holes was allowed to prevail. Internally, the employer-penalty program was not vigorously enforced. It remains to be seen how far the change in the official U.S. behavior will go, how long it will last, and what its effects will be.

The different perspectives of the two countries are shaped not only by the inherent facts that dominate the supply push-demand pull reality, but also by a number of other considerations. Many of these have changed in recent years and others are in dynamic flux as this is written. In addition, the perceptions of the public and legislators in the two countries about the migration phenomenon, even when not completely in conformity with the facts, have great weight in national responses.

Historical Background

Four Migration Waves

Mass migration from Mexico to the United States is about a hundred years old. There have been four major waves of migration during this period: three north-bound to the United States and one south-bound to Mexico. Beginning in the late 1890s and lasting until about 1930, the first major wave consisted mostly of seasonal agricultural laborers, refugees from the Mexican Revolution, and family-settler migrants moving north to the United States. The Mexican-born population in the United States shot up from about 100,000 in 1900 to about a million in 1930—about two-thirds of these legal immigrants.[2]

The second major wave was a large flow of about 600,000 settlers who returned south to Mexico during the Great Depression of the 1930s. The south-bound net flow of migrants to Mexico during this decade was larger than the north-bound net flow had been to the United States during the peak Mexican immigration decade of the 1920s.[3]

The third major wave occurred in the context of the organized bilateral recruitment of agricultural laborers during the Bracero Program (1942-1964) and consisted of hundreds of thousands of Mexican workers who were employed under 4.6 million contracts in the United States, and an additional number—probably several hundred thousand workers—who entered illegally and worked without contracts. Some settler migration also occurred during this period, but a significant proportion of undocumented settlers was expelled during Operation Wetback (1954) and the number of legal immigrants admitted from Mexico was relatively small.

Within this third wave, there were two distinct periods of unauthorized migration. Although there are no reliable estimates of this population, the trend in the apprehension of unauthorized Mexican migrants is suggestive: an explosive growth from 64,000 in FY 1945 to 485,000 in FY 1950 and then to 1,075,000 in FY 1954; an abrupt drop thereafter to 243,000 in FY 1955, 72,000 in FY 1956, and eventually to 30,000 in FY 1960. (Some authors have suggested erroneously that the one million

apprehensions of 1954 correspond to Operation Wetback. Actually, Operation Wetback generated about 175,000 apprehensions and expulsions during a two-month period in the summer of 1954, most of which occurred during FY 1955.)

The fourth major wave began after the last *bracero* agreement expired in 1964 and has consisted of large flows of undocumented and legal immigrants, temporary and long-term residents in the United States. Again, the growth in the number of apprehensions is suggestive of the growing flow of undocumented migrants: Apprehensions rose from 44,000 during the last fiscal year of the Bracero Program to 277,000 in 1970, 680,000 in FY 1975, 817,000 in FY 1980 and a peak of 1.7 million in FY 1986. The 1970 population stock of Mexican-born persons residing in the United States regardless of immigration status was almost one million—almost at the peak number estimated for 1930. It has grown by an annual average of more than 160,000 since then, to about 5 million today.

Seven Junctures When Perspectives and Responses Changed

During the past 10 decades, there have been about seven periods which can be characterized as junctures when government responses and official perspectives toward Mexican migration underwent significant change. In only one of these instances were the responses of the two countries relatively harmonious (early World War II, see below), and at two other junctures (1954 and 1964, see below) the changes sought by the United States led to openly acknowledged policy differences. In the remaining four cases of change in perspective and responses, one finds situations where the circumstances are mixed and include areas both of common ground and significant conflict.

The first juncture occurred in 1917. Several independent events of that year combined in a new way to redefine the policy issues related to Mexican migration. The 1917 Mexican Constitution adopted provisions for the protection of Mexican emigrant workers and the regulation of labor recruiters offering employment abroad. The United States adopted a new set of stringent requirements for the admission of immigrants and then, after entering World War I, promptly suspended them for Mexican and Canadian temporary workers. The recruitment of workers under these exceptions has sometimes been referred to as the first Bracero Program. About 75,000 Mexican workers were admitted temporarily under the World War I exceptions; many of them were later admitted as legal immigrants.

It was the first time since the Civil War that U.S. immigration policy had shifted to the admission of temporary foreign workers. Large numbers of workers also were recruited illegally; these persons waded across the Rio Grande/Rio Bravo in order to avoid paying the head tax at the port of entry. The Mexican government

was too involved in the civil war to pay much attention to migration, but it did express opposition to this recruitment and complained that labor recruiters were evading Mexican laws and that migrants were not being protected.

The decade of the 1920s represents a second juncture with several major changes in policy and perspective. On the U.S. side, the Border Patrol was established in 1924 and it began to deport thousands of Mexican workers who crossed illegally and were mostly employed in agriculture. By 1929, legislation was adopted making entry without inspection a crime punishable by a fine and imprisonment, not just an administrative offense which could be remedied by deportation.

Also during the period, Mexican legal immigration grew substantially—averaging more than 50,000 immigrants a year during 1924-1929—large enough to generate national controversy and to spark a movement in Congress to eliminate the exemption of Mexicans from the quotas imposed in the 1924 Act. Other governments had criticized the national origins approach to restricting U.S. immigration, and the Mexican government also complained that the extension of this quota would discriminate against its nationals.

Mindful of the bilateral conflicts that had arisen with China and Japan when Congress enacted legislation to stop immigration from those countries, the State Department actively opposed the proposal to restrict Mexican immigration.[4] In order to accomplish the same end in a manner less objectionable to Mexico, the State Department, through its consulates, began to apply stringently the exclusion against many Mexican visa seekers on the grounds that they were "likely to become a public charge." The number of immigrants admitted declined sharply from 67,000 in FY 1927 to 39,000 in 1929. The administrative restriction of Mexican legal immigrants, and the subsequent decline to less than 3,000 immigrants admitted annually during the depression years, made congressional action unnecessary. Administrative restriction deflected the congressional thrust for an annual quota to be applied to Mexican immigrants. However, it also had the unintended effect of encouraging Mexicans who planned to obtain immigrant visas to enter the United States illegally, seek employment, and later apply for a visa from within the country in order to get around the public-charge exclusion.

On the Mexican side, the government's policy toward emigration also underwent significant change during the decade. The most significant unilateral effort to repatriate Mexican emigrants occurred in 1921, when the U.S. economy went into sharp recession and tens of thousands of Mexicans were thrown out of work. The Mexican government promoted an ambitious program which resulted in the repatriation of 150,000 Mexicans—about twice as many as the United States had admitted during the World War I first Bracero Program.

However, when the U.S. economy recovered smartly in 1922, many of the workers brought home at Mexican government expense again emigrated to the

United States. Mexican government policy gave less emphasis to repatriation thereafter and a new emphasis was brought to bear on the protection of human and labor rights of emigrants in the United States through the activities of the Mexican consulates. The developments of the 1920s served both to define the experience with consular protection in the United States and to accentuate the Mexican view that, to some extent, emigration was virtually inevitable, and that the most appropriate policy response would be U.S.-Mexican bilateral management of contract labor migration. The Mexican government proposed such an arrangement in 1929,[5] but the major U.S. concern at that time was not how to promote seasonal labor migration, but how to reduce drastically the admission of long-term Mexican immigrants.

A third juncture took place immediately after the onset of the Great Depression. In 1931-32, the Bureau of Immigration conducted a much-publicized drive in Los Angeles and elsewhere to locate foreigners who had entered illegally and to expel them. The rationale for this deportation scare was that by encouraging immigrants to leave, jobs would be opened up for unemployed U.S. citizens. In addition, local governments, such as the County of Los Angeles, encouraged Mexican immigrant families supported by local charities to leave by paying for their transportation to the border and arranging for the Mexican government to cover the rest of the transportation to points in the interior. The Mexican government at first encouraged this repatriation, but it later viewed this as a situation created by U.S. employers who had recruited Mexican workers during the 1920s boom and then refused to assume any responsibility for them during the 1930s depression. The Mexican government also criticized discriminatory actions taken against Mexicans by local governments during the depression era.

A fourth juncture occurred at the outset of World War II, when perceived labor shortages and the need for bilateral wartime cooperation led to a major shift in U.S. policy: the negotiation of wartime bilateral agreements for the temporary employment of Mexican workers in U.S. agriculture and railroads. The protections adopted in the agreements reflected the requirements established in previous Mexican legislation. The two governments assumed responsibility for negotiating the terms of the employer-worker agreements, their enforcement, and the administration of the program, including the selection and transportation of Mexican workers, known as *braceros*. The efforts to jointly determine the conditions of wartime *bracero* migration quickly led to efforts to focus on undocumented migration, with the Mexican government pressuring the United States to enforce its border controls and adopting its own modest efforts to discourage illegal emigration. The Bracero Program was continued after the war ended, and the bilateral agreement was renegotiated several times until the last agreement expired in December 1964.

A fifth juncture occurred in the middle of the Bracero Program. In 1954, the negotiations for a new *bracero* agreement broke down, with the U.S. government claiming that Mexican consulates had exercised their authority inappropriately to withhold workers from growers in order to enforce Mexican interpretations of the agreement. The U.S. government announced a program to recruit Mexican workers unilaterally, a decision which incensed Mexican public opinion and led to a disastrous decision by the Mexican government to use force to attempt to prevent the unauthorized departure of Mexican workers. These efforts by the Mexican government produced riots and confrontations between Mexican officers and workers at the northern Mexican border. In the meantime, the U.S. Comptroller General declared that the U.S. government had no authority to spend appropriated funds for unilateral recruitment, and both governments returned to the negotiating table and reached a new agreement much closer to the objectives of the United States.

Subsequently, the U.S. government organized "Operation Wetback," a deportation campaign which removed many families of unauthorized immigrants living in the United States and transported them with Mexican government cooperation to points in the interior of Mexico. The campaign was accompanied by efforts to facilitate the contracting of *braceros* to substitute for expelled workers. During this juncture, the U.S. government was successful in pushing the Mexican government about as far as it would go to accommodate growers' interests in a new design for a Bracero Program and also promoted the common objective of reducing sharply illegal entries across the border.

A sixth juncture occurred during the period leading to and in the aftermath of the termination of the Bracero Program. In the early 1960s, pressure against the Bracero Program by labor and civil rights organizations mounted and opposition grew within the U.S. administration. In 1963, the Mexican embassy in Washington, D.C. expressed its view in a diplomatic note that terminating the program would not by itself bring Mexican labor migration to an end: unauthorized migration would grow in its place. The adverse effects on domestic farm labor working conditions that opponents of the program attributed to it would, in the view of the embassy, be exacerbated rather than eliminated by halting *bracero* recruitment. The embassy's note was published in the Congressional Record and the ensuing debate led to a congressional vote to postpone the termination of the program to December, 1964.

Although these differences were compensated by close cooperation in other areas of the bilateral relationship, U.S. and Mexican government opinions about the advisability of a Bracero Program remained in conflict for a decade. The Mexican government gave up its unsuccessful attempts to put the negotiation of a new

temporary worker program on the bilateral agenda in 1974 when it appeared that migration and energy issues might be linked.

A seventh juncture occurred in 1986, with the passage of the Immigration Reform and Control Act (IRCA). For more than a decade, a debate had been conducted in the United States over what would be the best approach to reduce illegal immigration. IRCA adopted a variation of the grand compromise which had been advanced consistently since 1977: employer sanctions and mass legalization. Since the largest national group in the unauthorized immigrant population was from Mexico, both of these provisions were seen as having a major impact on Mexicans. The perspectives held by the U.S. public and officials regarding Mexican migration shaped, and in turn were shaped by, the implementation of employer sanctions and mass legalization.

The events leading to the passage of IRCA and then its aftermath point in two different directions. On the one hand, they serve to underscore national differences in perspective—especially when comparing the most prominent views in both countries. U.S. public opinion showed a strong consensus against illegal immigration even though the public was divided on how to respond. The consensus of Mexican public opinion was that migration in one form or another was virtually inevitable and that problems were created by U.S. measures to expel millions of migrants who could not be absorbed by a weak Mexican economy. The public debate in both countries in the decade prior to 1986 pulled them apart rather than brought them together.

On the other hand, IRCA produced a convergence in the efforts to expand the bilateral dialogue on migration. Mexican officials, in the aftermath of IRCA, questioned the wisdom of having refused to adopt a more open position regarding the U.S. immigration legislative initiatives. Also, U.S. officials became concerned that, because of migration and narcotics control issues, bilateral relations were in some disarray. The immediate aftermath of IRCA seems to have marked a turning point for both governments in their efforts to engage each other more substantively on bilateral migration issues.

Changing Policy Stances

The bilateral interaction on migration issues has altered in recent years, most notably from a lack of consultation to considerable discussion between the two governments. At the margin, this has led to some actions that were missing before, such as greater attention to the human rights of Mexicans illegally in the United States, but the inherent differences between the two countries on the migration issue remain.

Mexico

Important and influential Mexican actors view migration as an outgrowth of the social-economic situation that exists in the country. Consequently, the general approach to the issue has found expression at a highly abstract level. Three such expressions can be mentioned. The first is a straightforward supply-demand model, that as long as the demand for the migrants exists in the United States, there is little that the Mexican authorities can do about it. The second frames the issue in development terms and concludes that as long as income disparities remain large, migration will continue. The third is that because of Mexico's position as an exit country from which emigration is inevitable, anything the government does has a low probability of success.

These conceptions have had great influence on Mexican thinking about migration since the end of the Bracero Program in 1964. The perspective has been summarized as follows: because the constitution guarantees Mexicans the right to free transit within the country, it would therefore be wrong for the state to prevent emigration; the Mexican government could not succeed in preventing emigration even if it tried; Mexicans emigrate in response to U.S. demand, over which Mexico has no control; and there is no reason for Mexico to try to control emigration because, through their actions (though not necessarily their rhetoric), the U.S. government and key political actors support undocumented immigration as beneficial to the country.[6]

This way of thinking, in operational terms, translated into a policy to have no policy on undocumented migration to the United States. In shorthand, Mexico had a "no-policy" policy. Mexico, therefore, stayed aloof from the debate on changes in U.S. immigration policy, and this political stance undoubtedly was optimal for meeting Mexican interests over many years.[7]

The no-policy policy began to shift in the latter half of the 1980s when Mexico started to liberalize its economy and to play a more active role in world economic affairs (e.g., entry into the General Agreement on Tariffs and Trade) and closer engagement with the United States, which led in due course to the conclusion of NAFTA. The passage of IRCA in 1986 probably was the turning point in Mexico's position. The Commission for the Study of International Migration and Cooperative Economic Development—the Asencio Commission named after its chairman, Diego Asencio—that was mandated in the IRCA legislation called for bilateral dialogue on positive ways to deter undocumented migration by promoting economic development in Mexico and this led to extensive contacts and much binational research on migration issues. These discussions were relatively neutral, focused mainly on studying issues rather than changing policy—but there were consultations where before there had been none.

The grand bilateral policy of NAFTA which came later, even though it dealt with economic issues, had its migration elements. One of the assumptions behind NAFTA was that it would facilitate Mexican economic growth and thus indirectly deter Mexican emigration. In the years since, the search for bilateral cooperation on migration issues has focused on practical, small steps rather than grand policies.

United States

The U.S. counterpart of the no-policy policy of Mexico was to act unilaterally on migration matters. This suited the U.S. style, but had a practical logic if the Mexican authorities preferred not to be involved. IRCA's provisions setting up the Asencio Commission enabled the United States to engage Mexico on the related development-migration issues. Bilateral engagement has since become the norm, with occasional lapses.

The degree of consultation is considerable and takes place at various levels. The memorandum of understanding (MOU) of May 1996 dealing with the protection of the rights of Mexican nationals in the United States was agreed at the 13th meeting of the U.S.-Mexico Binational Commission, a cabinet-level body.[8] The decisions of the Working Group on Migration and Consular Affairs include, in addition to carrying out this Binational Study of Migration, supporting the participation of Mexican officials in the Citizen Advisory Committees along the U.S.-Mexican border, and taking measures to assure safer and more orderly repatriation of undocumented migrants.

During President Bill Clinton's visit to Mexico, he and President Ernesto Zedillo of Mexico issued a joint statement dated May 6, 1997, laying out measures to "ensure a proper and respectful management" of the complex migration phenomenon.

The Working Group on Migration and Consular Affairs of the Bilateral Commission is the single most important body for consultation on migration matters. The persons in charge of migration policy and their subordinates now meet regularly. These meetings are facilitated by the presence of a migration attaché at the Mexican embassy in Washington, something unthinkable during the no-policy policy period. While there are sometimes glitches, the Mexican authorities are generally notified of U.S. changes that the INS contemplates. Border Liaison Mechanisms now exist to bring together local, state, and federal officials to discuss and, sometimes, resolve border problems, including migration matters. A Citizens' Advisory Panel has been established for dealing with abuses at the border and Mexican officials are sometimes invited to participate in its meetings.

The unknown in the current pattern of increased dialogue is whether this will lead to harmony between the two countries on migration issues. At the

extremes, there is little give in the official position of either country on the question of illegal entry into the United States. The United States cannot overtly consent to this, and Mexico cannot fortify its border to prevent exit. But there is room to maneuver short of these polar positions, as discussed in the following section.

Potential Common Ground

Notwithstanding these partially differing perspectives, there is some common ground, perhaps not in the "grand perspectives" but in the small and practical tasks and operations, such as making the border a safer place and enacting and enforcing actions against trafficking and smuggling of migrants. The Mexican authorities, for example, could limit the gathering of persons whose evident purpose is to make a run across the border.

Both governments would prefer migration to be orderly. There is also basic agreement on some fundamental principles. Both governments recognize the sovereign right and legitimate interest of each country to safeguard its own borders and to enforce its own migration laws. Within this context, it is acceptable and profitable to move toward the establishment of mechanisms for consultation on migration issues at different levels of government, including law enforcement personnel and diplomatic and consular representatives, and procedures for the exchange of information, experiences, and resources in various aspects of migration management.

To sum up, both countries now confront some similar challenges with regard to migration flows; these would include instilling respect for the human rights of migrants and assuring simultaneous facilitation and control of entry.

Changing Political-Economic Relations

While the grand policy of NAFTA does not include a migration element (save for Chapter 16 on the temporary entry of business persons), the transformation of respective attitudes that the agreement represents affects all elements of the bilateral relationship.

From the Mexican side, NAFTA represented a shift from maintaining a distant relationship to seizing the economic opportunity that a rich neighbor represents. From the U.S. side, NAFTA represents a way to develop closer political and economic ties with its neighbor. About 80 percent of Mexico's merchandise exports go to the United States. The industrial co-production that exists as a result of substantial U.S. direct investment has been at the heart of Mexico's recovery from the economic debacle of 1995. From the U.S. side, the burgeoning market in Mexico, despite the economic setback in 1995, represents a long-term opportunity.

Two-way merchandise trade (using U.S. data) in 1996 amounted to $130 billion, an increase of 20 percent over 1995.

Negotiating NAFTA also required a shift in bilateral political relations. Mexico's earlier reflexive opposition to U.S. international initiatives had to give way to a more cooperative relationship. The United States had to give political relations with Mexico a higher profile. NAFTA led to the creation of scores of new institutions, mostly to deal with the technical aspects of the agreement (such as rules of origin, customs procedures, and industrial and sanitary standards), but others with considerable political content. These are the various dispute-settlement arrangements, trilateral commissions for labor and the environment, and border institutions for stimulating and financing infrastructure.

Economic-political contacts have been facilitated by embedding them in institutional arrangements. So, too, have migration consultations been institutionalized. The migration issue is sensitive. In a recent poll involving 35,100 ballots, the U.S. Foreign Policy Association found that 32 percent of respondents felt that illegal immigration was the most important issue of U.S.-Mexican relations, more than any other single matter.[9] From the Mexican viewpoint, it is now important that conflicts over migration issues not contaminate the growing bilateral economic integration.

Administrative Structures

While Mexico and the United States both have presidential systems and federal structures, their governance differs substantially. The separation of powers is a basic aspect of the U.S. political structure, whereas the Mexican executive has been all powerful. This may change now that opposition parties control the Chamber of Deputies while the Institutional Revolutionary Party (PRI) controls the presidency. From early in U.S. history, the Supreme Court has had the power to declare laws unconstitutional, which has not been the case in Mexico. The use of the *amparo* in Mexico protects individuals on an ad hoc basis against overdrawn laws. It is much easier to amend the Mexican than the U.S. constitution; and the Mexican constitution is far more detailed than its U.S. counterpart. The Mexican Congress for many years was subordinated to the executive branch, compared with the periodic shifts in dominance between the two branches in the United States. The Mexican processes of government are now changing: the electoral system has been made more transparent; the opposition power in the Congress has increased; and judicial power is increasing. But the differences are still considerable. Except for a few agencies (such as External Relations), there is no permanent civil service in Mexico except at junior, non-policy levels. The turnover of personnel every six years, coinciding with each new president, is substantially greater than in the United States

when a new president takes office. Consequently, there is little institutional memory at senior levels in almost all Mexican government departments. The fact that the same party, the PRI, has been in office for the last 67 years mitigates the effects of the personnel turnover, but does not completely eliminate them because senior people shift from agency to agency. Most decisions in Mexico are made at much more senior levels than in the United States, and the lack of continuity at these levels is therefore aggravated.

The power of the federal government in relation to that of states and localities is significantly greater in Mexico than in the United States. This power is epitomized by the lesser ability of states and localities in Mexico to raise revenue than in the United States. This, too, is changing, but the disparity with the United States remains great; the differences may grow as even more power is going to state and local levels in the United States.

Migration matters in both countries are under federal jurisdiction and it is at this level where the consultation is most intense. Most initiatives, as noted earlier, come from the United States. The most important of these take the form of legislation with attendant appropriations for such things as patrolling the border or verifying the immigration status of job seekers.

There is thus something of a disconnect in both countries in that most bilateral discussion takes place at the federal level, while most of the effects are at state and local levels. It may be desirable to bring local authorities into more of the bilateral give-and-take.

Because immigration issues are so conflictual, pitting interest groups against each other and making it difficult to reach political compromises, the United States has long relied on independent commissions to provide guidance to Congress in anticipation of legislation. The Immigration Commission of 1907-1909 was created to advise Congress on how to respond to the situation created by the "new immigration"—nearly a million newcomers each year, mostly from southern and eastern Europe. It commissioned studies and issued dozens of reports on the characteristics of the new immigrant population.

These reports led to the adoption of a literacy test in 1917 as a screening device intended to reduce the number of illiterate and less desirable immigrants coming to the United States from eastern and southern Europe. When the literacy test did not produce the desired result, Congress abandoned it in favor of straightforward national origins quota laws (1921 and 1924) which essentially barred nonwhite immigrants and provided few visas for immigrants from eastern and southern Europe. Western Hemisphere countries were exempted from the quota and this led to a large increase in Mexican legal immigration starting in 1924.

In 1950, Truman's Presidential Commission on Migratory Labor was established to study problems of migrant farm labor. The 1951 report was critical of the Bracero

Program, but it stopped short of recommending its abolition. The Commission also emphasized the adverse effects of illegal migration on domestic farm labor. It presented detailed recommendations for penalizing employers of unauthorized workers—something the Mexican government had advocated before. In 1952, Congress did adopt criminal penalties for the transportation and "harboring" of unauthorized immigrants. However, it explicitly exempted their employment from the penalty legislation. The congressional delegation from Texas was instrumental in securing the passage of this loophole favored by farmers from that state, and it thus came to be known as the "Texas Proviso." The exception which legally permitted the employment of unauthorized workers was not repealed until the passage of IRCA in 1986.

In 1952, Congress passed omnibus immigration legislation but ignored President Truman's urgings to repeal the quota restrictions which had been in place since the 1920s. Truman appointed another commission whose 1953 report was influential in leading to the eventual repeal of national origins quotas in 1965.

Starting in 1965, the Select Commission on Western Hemisphere Immigration focused on the implementation of the 1965 Act and on "green card commuter" migration, which had grown after the termination of the Bracero Program. Its work influenced the 1976 amendment which extended the annual country ceiling of 20,000 visas to Western Hemisphere countries. All legal immigrants admitted in addition to that number were "nonquota" immigrants, most of them immediate relatives of U.S. citizens.

In 1978-81, the Select Commission on Immigration and Refugee Policy (SCIRP) held hearings and commissioned studies to review immigration policy in light of the growing unauthorized immigration, especially from Mexico, and the changing patterns of refugee flows. Congress did not wait for its recommendations to adopt the Refugee Act of 1980. The recommendations of the 1981 report were influential, however, in defining the range of acceptable proposals to respond to illegal immigration. These proposals shaped the legislative initiatives presented by Senator Alan Simpson and Representatives Romano Mazzoli and Peter Rodino between 1982 and 1985, which eventually resulted in the Immigration Reform and Control Act of 1986. The combination of employer sanctions and other control measures, and legalization for both long-term residents and temporary farm workers, constituted the political compromise which made legislative success possible after a decade and a half of unsuccessful attempts. SCIRP had envisioned the outlines of that successful political compromise.

The current U.S. Commission on Immigration Reform (1993-1997) is the latest iteration of this pattern. This Commission is charged with all aspects of immigration reform.

In Mexico, the debate on the migration phenomenon also has been the object of open and public participation sponsored both by legislative bodies and by the

executive power. On the legislative side, on December 29, 1984, the Senate created a commission to carry out a public national consultation on the situation of migrant workers, including immigrants into Mexico as well as Mexican migrants into the United States. This consultation was carried out in 16 hearings in central, south, and northern Mexico during all of 1985. The commission's report was presented to the Senate in December 1985.[10] One conclusion of this consultation was the proposal for a Charter of Rights of Migrant Workers to be agreed between Mexico and the United States.

In November 1990, the Mexican Senate again convened a hearing specifically on human rights of migrant workers. This hearing, significantly enough, took place at Mexico's northern border, in Tijuana. There were 92 participants. One characteristic of that hearing was the concern expressed by most participants of rising anti-immigrant attitudes in the United States, the growing use of firearms by U.S. border "vigilantes," and the vulnerable situation of infants, women and Indian migrants. There was a call for more stringent penalties against persons trafficking migrants and for closer dialogue between authorities of the two countries.[11]

On the executive side, in the first half of 1995, there were public consultations, with numerous participants, on the migration phenomenon as part of the process to prepare the national development program. The consultations covered immigration and emigration issues and the opinions expressed were diverse.

Objectives of the Two Countries

This is a shifting target because objectives change with the times and the context. Objectives sometimes must be defined as they relate to specific countries; for example, Mexico's objective to limit illegal immigration from Guatemala is quite different from its desire not to rock the boat with respect to the movement of Mexican migrants to the United States. Mexico, like the United States, has its own structure of employer sanctions to deter the hire of illegal immigrants. For the United States, because entry without documentation is predominantly from Mexico, the U.S. Border Patrol is concentrated at that border.

U.S. immigration policy has placed priority on family reunification since 1965 and, in practice, this has benefited Mexico; but this priority is not immutable. What follows focuses on objectives as articulated or practiced today.

Mexico

Migrant-sending countries rarely have explicit emigration policies. Few countries deliberately encourage emigration on a permanent basis, although many do so for temporary periods. Mexico did facilitate temporary emigration under the

Bracero Program and occasionally supports the idea of new programs to regularize the current illegal immigration into the United States.

Migration is so prominent in Mexico's domestic and foreign affairs that a public stance is unavoidable. This need for going public has to be weighed against a long-standing tradition of noninterference in the domestic affairs of other countries. The way out of this dilemma has been to pursue certain objectives related to migration, but not to have a migration policy as such.

Three major objectives are being pursued by Mexico. The most salient and openly stated is to protect the rights of migrants. This has more to do with migrants than with migration. Because of the large numbers involved, the execution of this objective requires the use of many resources, both outside the country and at home. The protection of migrants' rights abroad involves traditional consular and diplomatic efforts and a continuous monitoring of violations of these rights and the circumstances under which they occur. This is accompanied by public denunciations from time to time. Much of Mexico's consular activity in the United States deals with migration issues.

There are important domestic and foreign implications of this emphasis on the protection of migrant rights. On the domestic front, a special force has been created—Grupo Beta—to prevent abuses against would-be migrants who concentrate near the border to gain access to U.S. territory. Another recent initiative is a change in the General Population Law and its regulatory apparatus to increase penalties against those who traffic in migrant movements.

Achieving foreign migration objectives has led to substantial engagement with U.S. authorities. In addition, Mexico has sponsored international efforts to adopt rules regarding the rights of migrants and their families, irrespective of their legal situation. Mexico was active in the efforts, first in the International Labor Organization and then in the U.N. General Assembly, to pass the 1990 U.N. International Convention on the Protection of the Rights of all Migrant Workers and Members of Their Families. Mexico took a leading role to develop a shared position on the migration phenomenon within the North and Central American regions, as was acknowledged in the Joint Communique of the Regional Conference on Migration held on March 13 and 14, 1996, in Puebla, Mexico. This conference was attended by the governments of 10 countries. Protection of the human rights of migrants and others was the paramount issue at this conference.

A second Mexican objective is less openly stated, but of considerable importance. This is to avoid abrupt changes in U.S. immigration policy and in the flow of migrants. Mexico wishes to maintain stability of migratory conditions as it considers changes in its migratory regime. One author has conceptualized this objective as wanting "to keep the U.S. door open."[12] Recently this objective has taken the form of wanting to regularize this flow. The current readiness to discuss some form

of a guest-worker agreement can be seen in this light—to achieve steadiness in migratory policy and stability in the flow. The most prevalent proposals since 1994, set forth by diverse social groups, are to conclude a *bracero*-type agreement.[13]

The third objective that emerges from recent declarations of senior Mexican officials is to get recognition of the contribution that Mexican migrants have made to the U.S. economy and society.[14] This objective can be seen as a reaction to the recent negative U.S. climate against immigrants, and Mexican immigrants in particular. (This objective might be expanded to include the contribution that the migrants have made to the Mexican economy and society.)

The Mexican government has developed two main activities in relation to its citizens who are emigrating or have emigrated to U.S. territory: consular protection and a program for supporting communities of resident Mexicans or Mexican-Americans. Consular protection can be considered an immediate response to the wide variety of problems arising from the large flow of Mexican migrants, undocumented and documented, to the United States. The Program for the Mexican Communities Living Abroad can be seen as a medium- and long-term strategy to improve the living conditions of Mexicans and Mexican-Americans north of the Rio Grande.

Consular Protection

The main objectives of consular protection are to provide general assistance to the individual traveling or working abroad to make his or her stay and management of affairs easier in the receiving country, and to assure that the migrant has access to a system of justice outside of the limits of jurisdiction of his native country. Consular protection implies a claim filed against the local or central authorities located within the consular jurisdiction.

Traditionally, consular protection of co-nationals living in the United States has been considered a priority activity of Mexican foreign policy. There are currently 41 consulates throughout the territory of the United States; 12 are consulates general. This represents the largest network of consulates of any country in the world. Since its inception, consular protection has assisted migrants in their repatriation, hospitalization, recovery of labor compensation, legal trials, and in officially protesting abuses against them.

Analysis of Mexican consular protection in the United States leads to five main comments about this practice:

1. Protection is a traditional activity undertaken by the Mexican government. Consular protection in the United States is more than a century old, dating back to the Treaty of Guadalupe-Hidalgo of 1848. While the United States has focused in Mexico on the protection of property, investments, and goods owned by its nationals, Mexico, by contrast, has focused mostly on the protection of its labor force.

2. Protection is often used as part of political rhetoric. Speeches on foreign policy, and especially those regarding relations with the United States, usually include a reference to these protective activities. This is clearly the case in the yearly presidential State of the Union Address (*Informe Presidencial*). A review of speeches since 1964 shows that most presidents have appealed to the strengthening of consular protection as the principal response to the perceived abuses and violations of the human rights of Mexican legal and undocumented immigrants in the United States.

3. Protection follows the same pattern of reactions and counter-reactions occurring in the rest of the migration issue. The observed sequence is that Mexico responds to a perceived problem, say the Riverside incident discussed elsewhere; then comes a reaction to that response by the United States, which Mexico then possibly follows with a counter-reaction.

4. Since the end of the Bracero Program, the Mexican government has periodically announced the strengthening of this system of protection. During the Zedillo administration, there have been efforts to modernize the system by means of three main activities: training and updating programs; harmonizing criteria of what constitutes a case of protection; and improving technical infrastructure, such as the development of databases.

5. During the 1990s, there has been a tendency to intensify the dialogue between the authorities of both nations, and to establish techniques of coordination or consultation, such as the Border Liaison Mechanism, the Working Group on Migration and Consular Affairs, the Consulting Mechanism for the Immigration and Naturalization Services Activities and Consular Protection, and Mexico's participation in the Citizens' Advisory Panel (CAP).

Program for the Mexican Communities Living Abroad (PMCLA)

The Program was created in response to frequent demands from Mexican Americans to the Mexican government for more support for their communities living in the United States. The establishment of the PMCLA represents the Mexican government's recognition of the potential of Mexican Americans as a source of political support within the United States, and also the potential of the community to develop closer economic ties with Mexico. President Salinas created the Program in 1990, the year in which the negotiation of NAFTA was launched.

The goals of the PMCLA can be summarized as follows:

- To strengthen the links with the Mexican community in the United States, to defend the civil rights of its members, and to enhance Mexican culture in the United States;

- To contribute to the strengthening of Mexican citizens´ capacity to respond to the anti-immigrant climate in various regions of the United States; to institutionalize the relationship with Mexicans living abroad and to increase their visibility in Mexico; and
- To promote business ties between Mexicans and Mexican Americans, and to foster the latter's participation in certain areas of U.S.-Mexico relations.

The administration of Carlos Salinas made the program a priority in the bilateral relationship. The yearly budget of the program has exceeded $1 million since its creation. This, in terms of allocation of expenditures, makes it more significant than the Consular Protection Program. The PMCLA has developed seven main activities: community organization, sports, education and culture, information and communication, health care, business, and fund raising. The main accomplishments are:

- It has strengthened and broadened Mexican ties with organizations of Mexican Americans;
- It has created a network of cultural institutes all over the United States; and
- It has established a Council for Business Promotion.

United States

The main official U.S. objective is to keep open the front door for legal immigration but to close the back door of illegal immigration. While this objective can be stated simply, it is complex in reality. The desire to limit illegal immigration has long been official policy rhetorically, but not completely in practice. The implicit policies have not always dovetailed with the explicit pronouncements. The immigration legislation of 1996 contained some compromises on how open the front door should be, but the issue was not really resolved. It is quite possible that the issue of numbers will be revisited by the Congress in the near future. The priority given to family reunification is established policy, but there is substantial sentiment for more skill-based selection.

Two articles in a recent issue of the *Atlantic Monthly* give a good synopsis of the debate on U.S. immigration objectives. David Kennedy argues that the United States can still afford to accept immigrants, largely because they augment the labor supply and thus lead to higher economic growth. His main caveat is that immigrant concentration in a few locations challenges the existing culture, a phenomenon not present during earlier waves of immigration in the 19th century. The policy

implications of this analysis are ambiguous, but seem to point in the direction of admitting fewer immigrants in that this may be the only way to limit concentration.[15]

George J. Borjas, following an analysis he has set forth frequently in recent years, argues that because new immigrants are less educated than in the past, their admission leads to a decline in the wages of less-skilled native and national U.S. workers. His article focuses on the distributional effects of new immigrants whose admission, he states, favors employers at the expense of national workers, with only a modest net gain for the economy as a whole. The key policy implication of this argument is to change the criteria for admission in favor of skills and away from family unification.[16]

An analysis by the U.S. Department of Labor on how well the immigrant population legalized under IRCA fared five years later tends to support the Borjas argument. Two findings of that study are that the legalized immigrants compete for low-wage jobs, and that a disproportionate number of them are below the poverty level.[17] These are relatively short-term findings, over five years, and may or may not hold over longer periods, say, a generation or more.

Another objective of the U.S. authorities is to seek greater cooperation from the Mexican government than in the past. The earlier Mexican no-policy policy meant that Mexico was a bystander as its nationals moved illegally across the border. The new policy of dialogue permits the United States to seek more official engagement from Mexico. The Mexican legislation of October 1996 providing for more severe punishment of Mexicans who engage in migrant trafficking is one response to this new bilateral engagement.

The central U.S. objective—to put out the welcome mat to immigrants who enter legally and reject those who enter without documents or illegally overstay visas—requires a combination of facilitation and control. The control elements involve fences at the border, more resources for the Border Patrol, stronger penalties against employers who knowingly hire illegal aliens, a better system to help employers determine who is illegal, and inspections that take place at work sites. Control activities require the cooperation of agencies other than the INS, such as the Labor Department for enforcement of work standards in activities that tend to hire illegal aliens, such as the garment and construction industries, and service establishments such as restaurants and hotels. Cooperation is also sought from local jurisdictions, such as sheriffs.

The facilitation aspect was evident in the INS role in the IRCA legalizations and the effort to speed up border crossings. While it became controversial in the 1996 presidential election campaign, the INS facilitated the naturalization of eligible legal immigrants seeking citizenship and is working methodically to reduce the backlog of eligible legal admissions. The 1996 immigration law contains a number of facilitation measures: more full-time INS and Customs officials at the

border to reduce delays at peak crossing hours; greater use of commuter lanes to facilitate legal entry; more pre-inspection at foreign airports; and pre-clearance authority for foreign officials.

The Bilateral Agenda

There is a bilateral agenda. These common interests include the following:

1. Making the border safer. This is manifested on the Mexican side by Grupo Beta, on the U.S. side by the various facilitation efforts noted above, and jointly by the Border Liaison Mechanism and Mexican participation in the Citizens' Advisory Panel.

2. Cooperative efforts to prevent smuggling of migrants.

3. Cross-border community programs to facilitate legal crossings.

The cooperation to achieve these and related objectives are the consequence of the increased dialogue of recent years. The nature of the agreed objectives was set forth in the joint statement of the two presidents of May 6, 1997.

At the same time, the porousness of the border in conjunction with U.S. efforts to reduce illegal crossings at the most convenient points (such as Tijuana-San Diego and Ciudad Juárez-El Paso) has resulted in some tragic consequences. Crossings have been deflected to less hospitable terrains and a recorded 126 deaths resulted in 1996, and the 1997 death toll is accumulating at a more rapid pace.

Societal Attitudes and How They are Shaped

The vast divide that exists in societal attitudes in the two countries on the migration phenomenon is amply demonstrated in public opinion surveys, focus group conclusions, treatment in the media, and positions of key actors. There is no way to fully bridge the divide because it is rooted in the underlying situations of a sending and a receiving country and, consequently, reflects national self-interest in the current context. The best that can be expected is deeper understanding on each side of the attitude of the other and why this outlook exists.

Public Opinion Polls and Focus Groups

These will be shown separately for the United States and Mexico.

United States

While there are variations in the percentages depending on the circumstances when polls are conducted, the dominant U.S. attitude has been for restriction of

immigration. The restrictionist viewpoint has grown in recent years, dominated largely by attitudes in California. The restrictionist sentiment there exemplified by the passage of Proposition 187 in November 1994 had reverberations throughout the nation, but other states did not necessarily have the same reaction. The Governor of Texas, another important immigrant-receiving state, in August 1995 publicly deplored the Mexico- and immigrant-bashing attitude that he felt was prevalent in California. A similar reaction came at roughly the same time from Rudolph Giuliani, the mayor of New York City.

The ups and downs in the intensity of anti-immigrant sentiment seem to depend significantly on the employment (unemployment) situation at the time a poll is taken. It is therefore unwise to generalize about the depth of feeling on the immigration issue other than as a reflection of attitudes at a given moment. The vote on Proposition 187 came before California had recovered from an economic downturn. The contrary declaration of Governor George Bush, Jr., came when Texas had recovered from its earlier recession. It is important to note, also, that Texas relies much more than California on exports to Mexico and Texas is the main truck route for U.S. trade with Mexico.[18]

Two aspects of the U.S. polling data merit emphasis:

1. The shifts in the proportion of the U.S. public that believes the level of immigration should be decreased track reasonably well with the state of the economy (i.e., there is a rise in restrictionist sentiment as the economy worsens). Using Gallup Poll data, the proportion of persons favoring a decrease in immigration was 33 percent in June 1965, 42 percent in March 1977, 65 percent in 1981, 49 percent in June 1986, 53 percent in 1988, and 65 percent in 1993, and roughly the same two thirds in the summer of 1995.[19] The economy was relatively healthy in 1965 (relatively low restrictionist sentiment), depressed in 1982 (rising restrictionist sentiment), and growing in 1986 (and restrictionist sentiment declined). The concordance between the state of the economy and restrictionist sentiment was less pronounced in 1988, 1993, and 1995.

2. There is no evident correlation between public opinion as reflected in the polls and legislation. The polls over the years show much support for penalizing employers for knowingly hiring illegal aliens, but it took many years, until 1986, to reflect this in federal legislation; and even then, the law was not rigorously enforced. According to a Gallup poll in 1984, a majority of the public supported the idea of an identification card, but this has been resisted by the U.S. Congress. Despite the public sentiment over the past few decades for fewer immigrants, this has not been reflected in legislation. The estimate of the number of legal immigrants who will be admitted in 1997 under the 1996 law is 850,000, about the same as the previous year, despite the recent increase shown in the polling data of the proportion of the public favoring a reduction.

There are a number of reasons for the disparity between public opinion as reflected in polls and congressional action. These include the lobbying of interest groups, the logrolling that takes place to simultaneously satisfy many interests, differences that exist between regions of the country, concern over civil liberties with respect to identity cards, and the fact that polling percentages may not reflect deeply held sentiments.

The best reflection of public opinion in California, at least in November 1994, was the vote on Proposition 187, which was supported by a margin of 59 to 41 percent. Polls in California tend to show substantial divergences between Anglo and Latino voters. Thus, in 1994, the California Opinion Index indicated that 56 percent of Anglos felt that the IRCA amnesty was a bad thing, while 68 percent of Latinos thought it was a good thing to do. Again in 1994, 55 percent of Anglos favored amending the Constitution to deny automatic citizenship to children of illegal aliens born in the United States, while 76 percent of Latinos were against such a constitutional amendment.

On some issues, however, positions were not what intuition would lead one to believe. For example, on the use of ID cards for all persons living in the United States, 55 percent of Anglos thought it was a bad idea, while 56 percent of Latinos favored this. On the issue of the number of immigrants who should be admitted for legal residence, 55 percent of Californians thought this should be reduced, which was about 10 percentage points less than the Gallup Poll showed for the nation as a whole.

Recent developments in California, such as Proposition 187 and the incidents in Riverside County affecting illegal immigrants, have stimulated the effort for empowerment among Latinos. A poll commissioned by *La Opinion*, the nation's leading Spanish-language daily newspaper, and KVEA television, both in Los Angeles, reported in May 1996 that 57 percent of Latinos felt the best response was through political empowerment.[20]

Mexico

Data on Mexican public opinion regarding migration are either unsystematic or nonexistent. Recent opinion polls, therefore, have to be treated with caution. With this in mind, the high concentration of some poll results leads to the easy interpretation that positions merely repeat "messages of the media." However, this is not always the case. For example, a poll of Mexico City residents taken immediately after the April 1996 Riverside incident found that three out of four respondents consider that restricting the entrance of *indocumentados* is not in the interest of the United States. Eighty-five percent of the same Mexico City respondents also believe that Mexicans do little or nothing to help their nationals abroad. Only 15 percent declare to know that there are institutions which defend them.[21]

The different perceptions that exist in the two countries on the migration phenomenon manifest themselves quite vividly when it is possible to compare the answers to identical questions in a Mexican and U.S. survey. Such a dual survey was carried out in August 1996. The Mexican survey showed that only 2 percent of the respondents believed that stricter border controls would be effective to diminish migration, compared with 19 percent who believed so in the U.S. survey. The perceptions on the effectiveness of employer sanctions work in the same direction: the Mexican survey showed that only 4 percent believed that employer sanctions would work, while 18 percent believed so in the U.S. survey.[22]

According to a January 1997 opinion poll by MORI de México, only one in seven Mexicans believed that the measures taken by the government to protect its nationals abroad are somewhat effective, and 42 percent believed governmental efforts lack effectiveness. This same poll showed that 85 percent of Mexicans consider that U.S. immigration policy is either unfair or racist.

When questioned about the costs and benefits of Mexicans working in the United States, the respondents thought that migration was positive for both countries: 40 percent thought that the Mexican economy benefits, whereas 58 percent believed the U.S. economy benefits.

In response to a question on the convenience of seeking a formal bilateral temporary worker agreement, 76 percent thought that the Mexican government should seek such a pact with the United States.[23]

A similar picture of Mexican perceptions emerges from another survey carried out at the end of 1996. The survey was commissioned by Mexico's National Population Council (CONAPO) to evaluate family planning program in nine states in Central and Southern Mexico. Respondents consider that although Mexico receives some benefits from its migrants (42.6%), the United States benefits much more (75.3%). Regarding perceptions of Mexican protection of migrants, the opinions are almost equally divided between those who consider these efforts acceptable (41.3%) and those who consider that deficient (46.2%). Finally, the proportion of those who would like to see some sort of "temporary worker program" is overwhelming (81.2%).[24]

Elites and Non-elites

There is little solid data on the views of elites and non-elites generally in the United States. There is evidence that the views of Latino elites differ from those of the rank and file. This statement may be more accurate if nuanced in the way Peter Skerry has done: "Indeed, by defining the agenda for a poorly organized and largely disenfranchised group, the leaders exert extraordinary influence over how it [the rank and file, presumably] views the world."[25] Some examples given by Skerry are

positions on immigration and abortion. De la Garza and De Sipio also stress the importance of citizenship, or its lack, in shaping Latino views.[26]

Espenshade and Hempstead find in their analysis of survey data that the higher the education and income of Latino respondents, the more favorable they generally are to greater immigration.[27] This is consistent with what the authors hypothesized. The attitudinal differences between elites (defined in this example as the more educated and wealthier) and non-elites reflect the disparities in their perceived self-interest as much or more than in their ethnicity.

The significance of citizenship and disenfranchisement in determining mass as opposed to leadership positions may be undergoing a transformation. The increase in Latino (and other) naturalizations stimulated by the removal of benefits from legal aliens in the immigration and welfare bills had considerable influence in elections across the United States in 1996, especially in places where many Latinos live.[28] The rank and file Latinos, many more now enfranchised, turned out in greater numbers than in the past and, for the most part, their votes reflected the positions of the leadership. One unintended consequence of Proposition 187 and other anti-immigrant measures elsewhere has been to weaken the Republican Party in this and other states, at least for now, by antagonizing the fastest growing major ethnic minority—Latinos—in the United States.[29]

In Mexico, similarly, there is little solid data on the differences, if any, between the views of elites and non-elites. An approximation, however, of the views of the former can be obtained by looking at the way many enlightened employers interpret the migration phenomenon. Employers generally take the view that labor mobility is beneficial and rational. For them, there is no direct, or easy, solution to stopping Mexican migration. The answer to migration is indirect—through a healthier and more dynamic economy. Economic elites believe that if one wants to stop the current exodus, it is important that Mexican families recoup their economic security.

Employers see the migration phenomenon from the framework of the regional asymmetries within North America, and its solution within this same regional framework. Employers put forward two possible avenues to deal with the "migration problem." One is to legalize the phenomenon. The other (not in opposition to the first) is to promote the idea that within the North American space, resources—including labor—have to be shared among the three member countries.[30]

Public Positions of Influential Actors

Influential players can have a substantial impact on the public perception about migration issues. The positions of these actors undoubtedly carry much weight because their prominence attracts considerable media attention to their views. The

resulting public perceptions, whether or not accurate, do have an effect on legislative outcomes and on U.S.-Mexican relations.

In the United States, Governor Pete Wilson of California, by his advocacy of Proposition 187, gave official sanction to the measure. Governor Wilson had earlier made the issue of illegal immigration into California an important feature of his re-election campaign. Pat Buchanan, when he was seeking the Republican nomination for president in 1996, surely influenced many voters to support his anti-immigrant, especially anti-Mexican-immigrant, stance. In the end, Bob Dole, the eventual Republican candidate, supported Proposition 187. The anti-Mexican-immigrant position was by no means limited to Republicans. Senator Diane Feinstein of California opposed NAFTA largely on anti-immigrant grounds, and she has continued to take this position to this day. Her fellow Democrat from California, Senator Barbara Boxer, took a similar position.

Other key actors took opposite positions. As noted elsewhere, Governor George Bush of Texas criticized the anti-Mexican tone of many of the key players in California. President Clinton, on the opposite side of the position taken by his Republican rival, carried California in the presidential election.

Immigration from Mexico, and assertions about its fiscal burden for individual states and its social consequences for the nation as a whole, raised the visibility of Mexican relations in the United States, and not always in the most felicitous manner.

In Mexico, public statements and declarations of principles of key actors are plentiful. The positions selected—only three—are considered particularly relevant in framing the domestic debate and shaping the main public and private responses to the migration phenomenon. In his *Informe Presidencial,* President José López Portillo (1976-1982) synthesized in one short sentence what would later be repeated often as the Mexican view on the migration reality: "Mexico wants to export goods, not people." For years, the bulwark of the Mexican migration policy position has been the emphasis on the protection of migrant rights. During the debate on Proposition 187, this emphasis led Andrés Rozental, Undersecretary of Foreign Relations, to go on record in California in August 1994, in a way that many consider aggressive, even impolite and undiplomatic, in defense of Mexican migrants abroad. Finally, Jorge Bustamante, a well known scholar of the migration phenomenon, for years has been advocating the consideration of "a border perspective" in dealing with migration. His argument is that realities and perceptions at the border are peculiar to that region.

Media

The media treatment of migration is well exemplified by the nature of the coverage Proposition 187 received in Mexico and by the sober coverage in the United States of immigration reform.

Mexico — Proposition 187

The media in Mexico appeared to provide an accurate representation of the positions of the executive branch of government, the political parties, firms, the Catholic church, and the intelligentsia and academics about Proposition 187:

1. Executive branch of government: Both the Salinas and Zedillo governments saw the initiative as a racist and xenophobic expression. The government concluded that Proposition 187 affects the relationship between Mexico and the United States and compels dealing with the migration issue from a holistic and not a partial perspective.

2. Legislative branch of government and political parties: Both rejected the initiative and rallied to defend the human rights of the migrants. Both groups feared that Governor Pete Wilson's "electoral demagogy" would spread to other places in the United States. Their reaction had three elements: rejection of Proposition 187; the need to defend the human rights of Mexican nationals; and improvement of conditions in Mexico to obviate the need to emigrate.

3. Academic and intellectual communities: These groups characterized the Mexican government's response as unenthusiastic and felt that the rights of Mexican migrants had been subordinated to NAFTA negotiations and then to Carlos Salinas de Gortari's ambition to lead the World Trade Organization. They argued that failure to include the free mobility of labor between the signatory countries of NAFTA led to the discriminatory treatment of illegal workers.

4. Catholic church: Demanded a prompt dialogue between authorities of both countries and proposed the creation of a "Free Labor Agreement." Church leaders insisted that the Mexican government had to create conditions to avoid forcing citizens to cross the border illegally.

5. Private sector: Considered immoral the use of the migration problem by the U.S. politicians as a political device in the search for votes. Yet, they accepted that there is a serious unemployment problem in Mexico. They favored a strong defense of the rights of illegal workers in the United States.[31]

United States — Immigration Reform

In the period analyzed—from October to December 1995 and April 1996—the American press published a series of articles on the migration problem, focusing on the illegality aspect of the issue. In most reports, the dilemma was treated as a fiscal, economic and social problem which had adverse effects on American workers. There was also much stress on U.S. sovereignty loss because of lack of control of the border. Most articles supported unilateral U.S. measures to control illegal immigration.

The U.S. media reporting also showed two other tendencies: that measures like Proposition 187 were not a complete solution to migration problems; and the need to respect the human rights of workers.[32]

Advocacy by Nongovernmental Organizations

The manner in which this is done differs in extent and intensity in the United States and Mexico.

United States

Public interest groups are common in the United States and, in a sense, all significant legislation is the outcome of contests between such groups with differing interests. It has ever been thus in the United States, even if not to the extent that exists today; and, as Toqueville observed in a different setting, this capacity for organization of the public at large is one of the strengths of U.S. democracy. The immigration field lends itself to legislative and information contests because the interests at stake touch simultaneously on family and kinship matters, the cultural development of society, and the exercise of sovereignty over entry into national territory. There are many U.S. NGOs whose work is devoted exclusively to immigration issues (e.g., Federation for Immigration Reform, Center for Immigration Studies, and Voice of Citizens Together in California), and many more for whom immigration is one facet of their activities (such as the League of United Latin American Citizens, Mexican American Legal Defense Fund, National Council of La Raza, and, where issues of civil rights are involved, the American Civil Liberties Union). Business and agricultural interests take public positions on elements of legislation. The relative influence of these groups is significant in framing the compromises that emerge in immigration legislation.

As one goes through the 1996 immigration and appropriation bills, the influence of NGOs—either direct or as a result of public-education efforts—on outcomes becomes abundantly clear. Provisions to provide more funds to the Border Patrol than the administration requested demonstrates the strength of the anti-illegal immigrant sentiment. So do the pilot programs for confirmation of employment eligibility; but the fact that they are voluntary pilot programs also demonstrates that opinions differ sharply on this issue. The facilitation of legal entry at the border is in large part the result of a public-information campaign by NGOs. The restriction of benefits to non-citizen legal immigrants in both the immigration and welfare bills is partly the result of budgetary stringency and of pressure by NGOs. The provision making mutilation of female genital organs a criminal offense is the consequence of a public information effort by NGOs.

The list could be extended to past legislation, such as the SAWs program of IRCA and, before that, the Texas Proviso of 1952. The half-open door practice reflected compromises between various NGO groups which led to formal opposition to illegal immigration but not excessively so in practice. The constitutional case brought against implementation of major segments of Proposition 187 was directed by the ACLU in California.

The removal of the Gallegly amendment, which would have denied public education to alien children illegally in the United States, was largely a consequence of an organized public campaign by a number of NGOs. This outcome was aided considerably by the opposition to the amendment by the two Republican senators from Texas, Phil Gramm and Kay Bailey Hutchison.[33]

Mexico

NGOs have helped Mexican migrants for years. With the influx of Central American refugees into Mexico in the late 1970s and early 1980s, new NGOs arose whose work was directed to these groups of immigrants. This division of labor on migrants into and out of Mexico continues to the present, although there are NGOs that deal with both groups. NGOs increasingly combine work on issues of emigration from Mexico and those dealing with immigration into Mexico.

Mexican NGOs are becoming increasingly active and visible in the public debate. A group of at least two dozen NGOs, in combination with NGOs of other countries, gathered in Puebla, Mexico just before the First Regional Migratory Conference (March 1996) and presented a combined resolution. NGOs seek recognition by the government as interlocutors of the civic society.

These NGOs act as a pressure group for the migrants. The following two issues seem to take priority in their agendas: to inform and sensitize the population at large on the realities of the migration phenomenon; and to attempt to limit the adverse effects of migration on individuals, families, and communities. Many NGOs publicly denounce abuses and violations suffered by migrants during their journey toward the North, be they Mexicans or other nationals.[34]

Although not an NGO, nor devoted particularly to migration issues, the Comisión Nacional de Derechos Humanos (CNDH) has been monitoring the compliance and violations of migrants' human rights and, in so doing, has contributed tremendously to the creation of a culture of respect for human rights, including those of the migrants whatever their legal status. The CNDH in 1996 published its Second Report on the violations of migrants human rights along the northern border.[35] In 1995, it had published a report on the violations of the migrants' rights along the southern border.[36]

Legislative and Judicial Responses

U.S. Federal Immigration Legislation

Nationality

The U.S. Constitution states that all persons born in the territory of the United States are U.S. citizens and that Congress is empowered to establish a "uniform rule of naturalization." The terms by which nationality and citizenship are defined, acquired, and lost are established by federal legislation and court decisions interpreting this broad Constitutional provision.

Birth in the United States confers citizenship regardless of the status of the parents. Birth abroad of U.S. citizen parents confers derivative citizenship, according to complex rules that have changed over time. Usually, naturalization is a process by which a legally admitted immigrant who has resided in the United States for at least five years submits a petition and passes an examination in English and civics.

Admission of Immigrants

The United States sees itself as a country of immigration, and sees immigrants as potential U.S. (naturalized) citizens. U.S. immigration legislation has often arisen as a response to a perceived immigration problem of the moment, but usually has not focused specifically on Mexican immigrants. Early examples of policies that in some way focused on Mexican immigrants include the suspension of certain requirements of the 1917 Immigration Act to allow the temporary admission of Mexican workers during World War I, the creation of the Border Patrol in 1924, and the administrative restriction in 1927 which resulted in a decline in legal immigration from Mexico in the absence of quotas fixed by statute. Another example of a policy focused on Mexico was the recruitment of railroad and agricultural workers during World War II and the institutionalization of the Bracero Program in 1951.

Family reunification emerged as an important feature of U.S. immigration policy when numerical restrictions were first introduced in 1921, and it was maintained when immigration law was reorganized into the Immigration and Nationality Act of 1952. In 1965 it became a central principle of U.S. immigration policy. Before and since then, immediate relatives—unmarried children, spouses, and parents—of U.S. citizens have been admitted without statutory limit. Immediate relatives of permanent resident aliens and other close relatives of U.S. citizens and resident aliens have been admitted according to a complex set of rules which changed between 1965 and 1990 within a worldwide annual numerical ceiling. Preference categories set aside about 80 percent of the numerically limited visas for family-sponsored immigrants; employment-sponsored immigrants comprised most of the remainder.

In fiscal year 1995, the United States admitted over 720,000 immigrants, 12.5 percent, or nearly 90,000 of them born in Mexico (Table 1). The vast majority of these were close relatives of U.S. citizens or legal permanent residents—460,000 or 64 percent of the total, 90 percent of the immigrants from Mexico. Mexican immigrants comprised 26 percent of the total immigrants admitted under family-sponsored preferences (first through fourth preferences), including the 2A preference category of which 75 percent are admitted exempt from the per-country limit. By contrast, they comprised only 2 percent of the employment-based immigrants admitted and 3 percent of the categories not subject to numerical cap, which includes refugees and asylees.

Because the vast majority of Mexican immigrants over the years have been family sponsored and more have applied under numerically limited categories than visas have become available, backlogs have developed as applicants have waited for an immigrant visa. This first became apparent in Mexico's case shortly after 1976, when all countries were assigned an annual numerical limit of 20,000 immigrant visas for applicants other than immediate relatives of U.S. citizens. By 1982 271,582 active applications from Mexico were pending; by 1989 this had grown to 403,523. The 1986 Immigration reform and Control Act increased pressure on the visa backlog system even as it allowed for the legalization of 2.3 million persons from Mexico. This has led to a further increase in applications for permanent immigration status outside the numerical limitations of those legalized under IRCA. Perhaps 800,000 visa applicants in the backlog for Mexico resulted from this second stage of immigrant visa applications.

The 1990 Immigration Act increased the per-country annual limit for Mexico and other countries to approximately 28,000.[37] It also allowed for 55,000 extra visas for each year during 1992-94 minus the amount by which immediate relative immigrants exceeded 239,000 in the previous year for spouses and children of aliens legalized under IRCA. This helped reduce the backlogs and, for a brief period, nearly equalized the visa waiting period for applicants from all countries. By January 1995, however, the immigrant waiting list had grown to a total of 3.7 million applications, one million, i.e., 28 percent, from Mexico (Table 2).

Mexican applications are oversubscribed in all of the family preference categories—the shortest wait (first preference) is now about $4\frac{1}{2}$ years. In March 1997, visas were available for Mexican 2A applicants (spouses, children and unmarried sons and daughters of permanent resident aliens) who had a priority date before June 8, 1992. Third-preference applicants (married sons and daughters of U.S. citizens) and fourth-preference (siblings of adult citizens) have waited for about a decade for a visa. In March 1997, these applicants had February 1, 1988 and October 1, 1985 priority dates, respectively. It is not possible to predict how long it will take any given set of applicants to obtain a visa since they may later

Table 1
Immigrants Admitted to the United States from All Countries and Born in Mexico, by Legal Category, FY 1995

Immigrants Admitted	All Countries	Mexico	%
1. All immigrants admitted (1)=(2)+(22)	**720,461**	**89,932**	**12.5**
2. Subject to numerical cap	**593,234**	**86,079**	**14.5**
3. Family-sponsored preferences	**238,122**	**61,877**	**26.0**
4. Unmarried adult children of U.S. citizens	15,182	1,979	13.0
5. Spouses and unmarried children of alien residents, including exempt from limit	144,535	52,167	36.1
6. Married adult children of U.S. citizens	20,876	2,031	9.7
7. Siblings of U.S. citizens	57,529	5,700	9.9
8. Immediate relatives of U.S. citizens	**220,360**	**22,016**	**10.0**
9. Spouses	123,238	13,824	11.2
10. Parents	48,382	3,844	7.9
11. Children	48,740	4,348	8.9
12. Other family-sponsored subject to cap	**2,171**	**454**	**20.9**
13. Children born abroad to alien residents	1,894	369	19.5
14. Legalization dependents	277	85	30.7
15. Employments-Based immigrants	**85,336**	**1,708**	**2.0**
16. Priority workers	17,339	193	1.1
17. Professionals with advanced degrees of exceptional ability	10,475	56	0.5
18. Skilled, professionals, unskilled	50,245	1,086	2.2

submit applications under a more advantageous category, a close relative may naturalize and petition for their admission outside of the annual numerical ceiling, or Congress may amend the law again.

Control of Unauthorized Immigration

IRCA contained important legislative changes in policy regarding the deterrence of unauthorized immigration. Its principal provisions were (1) the adoption of penalties for employers who knowingly hired unauthorized immigrants and who did not review the documentation of all new hires; (2) the legalization of millions of unauthorized migrants; and (3) additional resources for the apprehension and removal of illegal entrants at the border with Mexico. The legalization provisions

allowed migrants who had resided illegally in the United States since January 1982 and met other requirements, or who had been employed in perishable agriculture for at least 90 days during the twelve months ending in May 1986 (Special Agricultural Workers, SAWs) and met other requirements to obtain temporary and later permanent resident status.

IRCA was the end product of a 15 year debate over how to respond to illegal immigration, especially from Mexico, which had been marked by legislative proposals considered but not enacted by Congress in 1971 and 1972, the Carter immigration plan of 1977, the recommendations of the Select Commission on Immigration and Refugee Policy (SCIRP) in 1981, the Reagan immigration plan of 1981, and successive bills introduced by Senator Alan Simpson and Representatives Romano Mazzoli and Peter Rodino.

There is considerable debate regarding the consequences of employer sanctions enforcement and the reasons for their perceived failure. As a policy response to unauthorized immigration, especially from Mexico, four general observations can be made. First, the response itself is a recognition that access to the labor market accounts for much of the unauthorized immigration to the United States. Second, 10 years of experience with the implementation of employer sanctions underscores the difficulties involved in imposing a new employment standard and in shifting to employers part of the burden of regulating immigrants in the labor market. Third, employer sanction legislation has had some unintended but foreseeable effects, such as the growth of an industry in fraudulent documents and the expansion of the role of subcontractors and labor market middlemen who shield employers from the penalties of the law. Finally, though it may be possible to argue that unauthorized migration would have been higher in the absence of employer sanctions, it is clear that these penalties in combination with other circumstances since 1987 have not reduced the population of migrants illegally in the United States or even reduced the rate of growth of this population.

There is much less debate over the immediate consequences of legalization under IRCA. A total of 1.6 million pre-1982 residents and 1.1 million Special Agricultural Workers from all countries legalized their status and eventually were admitted as permanent resident aliens outside of the numerical limitations. Mexican nationals comprised 70 percent of the pre-1982 population and 81 percent of the SAWs legalized under IRCA. Legalization made it possible for many of these persons to stay and work in the United States without fear of deportation, travel freely in and out of the country, to apply for immigrant visas for close relatives, and to apply for naturalization, which many did, starting in the mid 1990s.

The increase in resources dedicated to border enforcement under IRCA was further expanded and a new enforcement approach was adopted in 1993 with Operation Hold-the-Line in El Paso and later with Operation Gatekeeper in San

Diego. The new strategy combines a large growth in the number of Border Patrol officers, an expansion in the kinds of devices and technology employed to detect bordercrossers, and a forward and visible deployment of officers near the boundary. In combination with an extensive metal fence constructed at the border, this approach emphasizes deterring illegal entry whereas previous strategies emphasized apprehension and removal after illegal entry.

Though it is early to evaluate the effect of this heightened border enforcement effort on the size of the unauthorized immigrant population in the United States, it has had the effect of changing the strategies employed by border crossing persons: there is an increase in the number of illegal crossing attempts using fraudulent documents at the ports of entry, of smugglers, and a growth in the flow through difficult desert and mountainous terrain.

1996 Immigration Legislation

The Illegal Immigration Reform and Immigrant Responsibility Act of 1996 (IIRIRA) goes beyond IRCA and constitutes an even more radical overhaul of immigration law as regards the control of unauthorized immigration. IIRIRA authorizes increased levels of appropriations for new resources and personnel related to immigration enforcement. Depending on annual appropriations in each case, it increases the number of Border Patrol agents by 1,000 per year and support personnel by 300 per year between FY 1997 and FY 2001 (sec. 101). It authorizes an increase in the number of INS investigators and support personnel assigned to investigate employer sanctions violations and document fraud (sec. 131). It authorizes an increase of 300 new full-time investigators assigned to visa overstay cases (sec 132). It mandates the Attorney General to increase detention space to 9,000 beds by the end of FY 1997 (sec. 386). It authorizes $150 million for costs associated with the removal of aliens, including investigations and detention (sec. 385). It increases the number of asylum officers by 600 in FY 97 (sec. 605). It increases the number of Assistant U.S. Attorneys by at least 25 to assist in the prosecution of crimes relating to immigration and alien smuggling (sec. 204).

IIRIRA makes significant modifications designed to strengthen the effectiveness of existing employer sanctions provisions. It removes the liability for technical violations of paperwork requirements where employers demonstrate good faith (sec. 411). It reduces the number of acceptable employment verification documents and requires the federal government to comply with the same paperwork requirements (412). It requires the Social Security Administration to develop a prototype of a counterfeit- resistant Social Security card (sec. 657). It provides for three types of pilot programs designed to test the strengths and weaknesses and costs of various approaches to verifying work authorization (sec. 401-403). Participation is voluntary

for private employers (although certain employers who have violated immigration laws may be required to participate) and mandatory for job applicants.

In addition to increasing substantially the number of Border Patrol personnel, the IIRIRA mandates the construction of triple fencing along the San Diego border (sec. 102) and calls for reports and studies to evaluate the deterrent effects of INS border management (sec. 107). It also provides funds and establishes new procedures to tighten the inspection of nonimmigrants (sec. 123, 124, 125, 110). At the border it also provides for an improved border crossing card and an increase in the number of border inspectors in order to reduce border crossing delays at peak hours (121).

IIRIRA abolishes the doctrine of "entry," and replaces it with the concept of "admission," eliminates the previous exclusion and deportation proceedings and replaces them with a single hearing to effect removal (sec. 301, 304). The expedited removal of inadmissible arriving aliens is authorized. Section 302 introduces an important new condition for aliens which took effect on April 1, 1997: the exclusion without a hearing for individuals with fraudulent documents or no documents at all, unless the alien declares an intention to apply for asylum or state a "credible fear of persecution." If the alien cannot establish continuous physical presence for the two years before notice or detention, the INS has the discretion to deny a hearing to any alien who was not admitted or paroled—e.g., one who entered without inspection. The Attorney General has sole discretion and this is unreviewable.

The authority of the INS to detain persons, moreover, is no longer subject to judicial review. Nor may a court set aside a decision to detain or release an alien, or to grant or deny bond or parole (sec. 303). Congress anticipated that there may not be sufficient detention space for the INS to hold everyone under this section and therefore authorized a transition period to delay its implementation if there is insufficient space and personnel. Otherwise, this section became effective on April 1, 1997.

Section 301 introduces a set of new conditions which took effect on April 1, 1997, and which bar permanently or for several years the subsequent legal admission of persons who remain unlawfully in the United States. An alien unlawfully present in the United States for more than 180 days and less than one year, and who leaves the United States voluntarily before removal proceedings, is inadmissible for three years. An alien unlawfully present for one year or more and leaves voluntarily before removal proceedings is inadmissible for 10 years. Certain aliens ordered removed at the end of removal proceedings initiated at the time of arrival will be inadmissible for five years. Otherwise, an alien who is ordered removed or who has departed after a removal order was issued, is inadmissible for 10 years—20 years if subsequently removed, permanently if the alien committed an aggravated felony. Aliens unlawfully present for an aggregate period of more than one year or

who have been ordered removed and who subsequently enter or attempt to enter the United States without lawful admission are barred permanently from admission. The Attorney General is given discretion to give prior consent for reapplication only after 10 years have lapsed.

Two previous forms of relief from deportation have been modified significantly. The period of continuous presence required for "suspension of deportation" is extended from seven years to 10, and the applicant must demonstrate that removal would result in "exceptional and extremely unusual hardship" to the alien's U.S. citizen or permanent resident alien spouse, parent or child (sec. 304). Previously the applicant, a deportable alien, could demonstrate extreme hardship to himself or herself.

The second form of relief from deportation—voluntary departure—is still available to many unlawful migrants. If sought before completion of removal proceedings, it must be undertaken within 120 days of notice to appear. If sought at the conclusion of removal proceedings, several specific conditions must be met: the alien must have been physically present in the United States for at least one year before the notice to appear, can demonstrate good moral character for five years before application, is not deportable because of an aggravated felony or other serious grounds, and has established convincingly that he intends to depart. Failure to depart in a timely fashion will result in civil fines between $1,000 and $5,000 (sec. 304). Other penalties include fines not to exceed $500 per day for aliens who willfully fail or refuse to depart after final orders of removal (sec. 380). The Attorney General is given authority to limit eligibility for voluntary departure for any class of aliens, and this authority is not subject to review by the courts (sec. 304).

The INS is required to detain any alien who is inadmissible on criminal-related grounds or criminal grounds of deportation. The discretion is not subject to judicial review (303).

IIRIRA seeks to facilitate the cooperation and communication between the INS and state and local government agencies and the transfer of alien prisoners to foreign countries. Section 133 authorizes the Attorney General to enter into agreements with state and local authorities in order to authorize state and local law enforcement officers to perform immigration enforcement functions, including investigation, apprehension and detention. The IIRIRA prohibits federal, state, and local officials from prohibiting any government entity from sending or receiving information from the INS regarding the citizenship or immigration status of any individual, or of maintaining such information (sec. 642). It also requires federal regulations to tighten the design of birth certificates issued by the states, and to consult with state agencies for this purpose (sec. 656). Section 330 recommends the negotiation of additional prisoner transfer treaties which would allow for transfers without the prisoner's consent.

Finally, IIRIRA levies new costs and criminal penalties on unlawful immigrants. It precludes the payment of Social Security benefits to aliens not lawfully present (sec. 503). It requires states to not provide in-state tuition and other college benefits to an alien not lawfully present unless the state would also provide the same benefit to citizens residing in another state (sec. 505). It increases either civil or criminal penalties, or both, for individuals who are unlawfully in the country, who smuggle or transport them, or who provide or utilize false documents. Section 105 provides for civil penalties for illegal entry; sec. 108 for criminal penalties for high-speed flights from immigration checkpoints. Certain criminal violations of the Immigration and Nationality Act may be prosecuted as racketeering offenses (sec. 202). The criminal penalties for alien smuggling are increased to 10 years' imprisonment; 15 years for a third or subsequent offense (sec. 203). Section 211 allows for increased criminal penalties for document fraud and sec. 215 for false claims to citizenship.

The family-sponsored immigration preferences were amended to require that sponsors providing affidavits of support be able to support both the sponsor's and the immigrant families at 125 percent of the federal poverty guideline. This obligation does not end until the sponsored immigrant becomes a U.S. citizen or is employed for 40 quarters (i.e., accumulates ten years of employment). This is a stringent new provision.

Many provisions of IIRIRA and its companion welfare reform legislation are based on the assumption that unauthorized foreigners have abused the adjudicative process and that immigrants take advantage of the welfare system. These two laws, and the anti-terrorist act adopted in 1996, are mutually reinforcing. The hundreds of pages of regulations required to carry out the IIRIRA that were issued by the Justice Department in early 1997 reflect the extraordinarily detailed statute which broadens the authority of the INS over aliens and reduces considerably the legal means available to aliens to challenge administrative decisions which, if applied to citizens, would be quashed by the courts. IIRIRA eliminated many of the procedural due-process safeguards, including in many instances the right to a hearing and the judicial review of administrative decisions. These provisions sharpen differences between citizens and authorized aliens, and declare that unauthorized immigrants cannot call on outside the protection of many of the safeguards available to citizens under the Constitution.

U.S. Supreme Court Decisions and Immigration Law Enforcement

The authority of the law enforcement agents at an external border of the United States or its equivalent (such as at an international port of entry) to conduct searches and seizures and to detain is considerably broader than the authority of police officers

in their normal conduct of criminal law enforcement within the country. The courts have ruled that warrantless searches without probable cause at an external border do not violate the Fourth Amendment prohibition of unreasonable searches and seizures. The authority of immigration officers to stop vehicles, question persons, and conduct searches and seizures at places other than the external border or its equivalent, is broader than that of the police enforcing criminal law, but less broad than at the external border.

Over the past three decades, the Supreme Court has defined different standards of constitutionally permissible searches and seizures depending on whether the law enforcement activity was conducted by a roving patrol near the border, at a traffic checkpoint, and in workplaces, whether the basis for the warrantless search was individualized or not. In the early and mid 1970s, the Court tended to restrict the search and seizure authority of the INS. Since then the trend has been toward the expansion of that authority. This particular area of judicial review raises important questions about the balance between the goals of immigration law enforcement and protecting the privacy of individuals who face the possibility of warrantless searches, questioning, and detention by immigration officers.

Three Supreme Court cases—Almeida Sánchez v. U.S. (1973), U.S. v. Ortiz (1975) and U.S. v. Brignoni Ponce (1975)—defined the initial standard by which the courts sought to balance the strong governmental interest in controlling unauthorized immigration and the constitutional right of individuals against unreasonable searches and seizures. In its opinion in Brignoni, the Court acknowledged the friction between the Fourth Amendment and the broad statutory authority granted to the INS by section 287 of the Immigration and Nationality Act to effect searches without a warrant.[38] (Table 3 summarizes the cases discussed in this section. A more extensive summary of Fourth Amendment cases appears in Volume 3, pages 1241 to 1247.)

At issue in Brignoni was whether a roving patrol may stop a vehicle near the border and question its occupants relying solely on the apparent Mexican ancestry of those occupants. The Court held that a roving patrol need not base a stop on probable cause if the officers are "aware of specific articulable facts, together with rational inferences from those facts, that reasonably warrant suspicion" that the vehicle was carrying unauthorized migrants, and that apparent Mexican ancestry did constitute one of several factors that could be employed to determine whether reasonable suspicion existed. However, the Court concluded that the apparent Mexican ancestry of the occupants, alone and unsupported by other facts, was not sufficient to believe the occupants were aliens and to justify a stop. An officer may stop a car briefly and investigate the circumstances that provoke suspicion when his or her observations lead him reasonably to suspect that a particular vehicle may contain aliens who are illegally in the country.

Table 3
Summary of selected Fourth Amendment Supreme Court cases, 1973-1990 (U.S. Supreme Court unless otherwise indicated)

Case	Holding/significance
Almeida-Sánchez v. U.S. (1973)	Limited the power of INS roving patrols to stop and search vehicles not at border.
U.S. v. Ortiz (1975)	Court applied probable cause standard to traffic checkpoint searches.
U.S. v. Brignoni-Ponce (1975)	Apparent Mexican ancestry of occupants of vehicle near the Mexican border not sufficient under Fourth Amendment to stop and question re: citizenship and immigration status.
U.S. v. Martínez-Fuerte (1976)	At a fixed checkpoint, individualized suspicion is not necessary to stop a vehicle. Profile of individuals, such as apparent Mexican ancestry, is sufficient. Exception made for fixed checkpoints.
U.S. v. Cortez (1981)	Objective facts and circumstantial evidence based on profile of individual are a legitimate basis for suspicion of a particular person and justifies investigative stop of vehicle. Dilutes Brignoni-Ponce.
ILGWU v. Sureck (1982)	Ninth Circuit held that the workforce in a building during a factory sweep by INS was seized for the duration of the survey. Fourth Amendment requires individual could be questioned only on basis of reasonable suspicion that the individual was an unauthorized alien.
INS v. Delgado (1984)	Overturned ILGWU v. Sureck. INS practice of closing factory exits not a detention but interrogation device; systematic questioning not based on individualized suspicion meets Fourth Amendment standard.
INS v. López-Mendoza (1984)	Exclusionary rule does not apply to deportation hearings.
U.S. v. Verdugo-Urquidez (1990)	Fourth Amendment extends only to individuals with substantial connections with U.S. and may not extend to all unauthorized aliens present in the United States.

In Almeida-Sánchez and Ortiz, the Court held that a search of an auto away from the border or at a traffic checkpoint requires a warrant or probable cause to meet the reasonable searches and seizures standards of the Fourth Amendment.

In two subsequent decisions—U.S. v. Martínez-Fuerte (1976) and U.S. v. Cortez (1981)—the Supreme Court backed away somewhat from the standards previously enunciated. In Cortez, it diluted the holding in Brignoni by allowing for a stop based solely on the profile of an individual. The Supreme Court found, examining "the whole picture," that the detaining officers had met the Brignoni-Ponce requirement of founded suspicion. In Martínez, the Court carved out an important exception for stopping vehicles at reasonably located traffic checkpoints. It held that at such checkpoints, INS agents needed no individualized suspicion to stop a vehicle and question its occupants.

The lower court decision in Martínez had followed Almeida, Ortiz, and Brignoni. In reversing Martínez, the Supreme Court distinguished this case from previous holdings by finding that traffic checkpoints conducted by the Border Patrol present a minimal intrusion on the privacy of motorists and that the purpose of the stops was legitimate and in the public interest. The Court also weighed in on the side of practical considerations of law enforcement to justify the finding that traffic checkpoints do not have to meet traditional Fourth Amendment standards. The opinion observed that the need for this enforcement technique was demonstrated by the records in the cases before the Court, and that on major routes the traffic is too heavy to allow for a particularized study of vehicles.

The exception enunciated in Martínez applies only to traffic checkpoint stops. Any intrusion beyond the original stop must be based on consent or probable cause. Even so, in his dissent, Justice Brennan argued that in the instance of checkpoint stops, the majority opinion had rendered the Brignoni requirement of minimum reasonable suspicion meaningless. The exception created by Martínez-Fuerte, Brennan argued, would "inescapably discriminate against citizens of Mexican ancestry and Mexican aliens lawfully in this country for no other reason than that they unavoidably possess the same 'suspicious' physical and grooming characteristics of illegal Mexican aliens."

Martínez-Fuerte marked the beginning of a series of exceptions and a shift away from the requirement of individualized suspicion and traditional interpretations of the Fourth Amendment in the enforcement of immigration law at places away from an external border.

In 1982 the Ninth Circuit Court of Appeals issued a ruling in the case of International Ladies' Garment Workers' Union v. Sureck which was consistent with the earlier requirements. This case concerned a factory worksite survey in which INS agents moved through the factory floor and inquired as to the citizenship and immigration status of the workers while other agents were stationed at the

exits. The Court admitted that section 287 of the INA authorized the INS to question any alien or person believed to be an alien as to her right to be or remain in the United States, pursuant to the Fourth Amendment. Accordingly, the appeals court found that an individual could be questioned only on the basis of a reasonable suspicion or probable cause that that particular employee was an unauthorized alien. In ILGWU v. Sureck the court found that the work force at the plant was seized for the duration of the survey and that the agents had created a detentive environment by their verbal authority, badges, use of the element of surprise, the sustained disruption of the working environment, and the questioning of selected individuals based upon their clothing, facial appearance, hair color and styling, demeanor, language and accent.

In INS v. Delgado (1984), the Supreme Court overturned the Ninth Circuit ruling. The majority opinion stated that the factory survey did not result in a seizure of the entire work force, and that the individual questioning of the employees did not amount to a detention or seizure under the Fourth Amendment. A concurring opinion by Justice Powell reasoned that the surveys were permissible by applying the analogy of a permanent checkpoint away from the border. He found that workers have no more expectation of privacy in a workplace than people in automobiles, and therefore the constitutional standard was met since both circumstances posed minimal intrusiveness and maximum government interest. While federal courts continue to refuse racial or national-origin appearance to justify warrantless stops, the Supreme Court is apparently satisfied with the constitutionality of the systematic questioning (as opposed to questioning based on individualized suspicion) that occurs during INS factory surveys.[39]

Another area where INS authority has been interpreted broadly involves the exclusion of evidence obtained unlawfully. The issue in INS v. López-Mendoza (1984) was whether an admission of unlawful presence in the United States made after an allegedly unlawful arrest must be excluded as evidence in a deportation hearing. The Court applied a balancing test which weighed the social benefits of excluding unlawfully seized evidence against the likely costs. On the benefit side was the goal of deterring future unlawful police conduct. On the cost side was the loss of evidence and all of the secondary costs flowing from the less accurate or more cumbersome adjudication that occurs as a result. The Court considered that the costs did not justify the benefits. It also noted that deportation hearings require fewer protections for the individual than do criminal proceedings.[40] It concluded that persons threatened with deportation could not exclude evidence obtained in violation of the Fourth Amendment at civil deportation hearings.

In a later case not specifically about unauthorized aliens but that had important implications for their rights, U.S. v. Verdugo-Urquidez (1990), the Supreme Court suggested that unauthorized aliens have no Fourth Amendment rights at all. Before

Verdugo reached the Supreme Court, the Ninth Circuit considered the question whether the Fourth Amendment applied to searches and seizures by U.S. agents of property located in a foreign country and owned by a non-resident alien. The Ninth Circuit reasoned that in its previous ruling in López-Mendoza, the Supreme Court had recognized that unauthorized immigrants have Fourth Amendment rights and therefore, that in Verdugo it was "difficult to conclude that Verdugo-Urquidez lack[ed] these same protections" since Verdugo was legally present in the United States.

In its review of Verdugo, the Supreme Court disagreed. Justice Rehnquist stated that the issue in López-Mendoza had been a narrow one—whether the exclusionary rule applied in civil deportation hearings—and "did not encompass whether the protections of the Fourth Amendment extend to [unauthorized immigrants] in this country."[41] The Court noted that the Fourth Amendment extends only to "the people," which "refers to a class of persons who are part of a national community or who have otherwise developed sufficient connection with this country to be considered part of that community." The Court reasoned that if the framers of the Constitution had intended the Fourth Amendment to be more universal in its application, they would have used the term "persons" as they did in the Fifth and Sixth Amendments.[42] The Court seemed to have concluded that Fourth Amendment protections extend only to those "people" who have "substantial connections" with the United States.[43]

Between the Almeida-Sánchez, Ortiz, and Brignoni-Ponce at one end, and Delgado and Verdugo-Urquidez at the other, the U.S. Supreme Court has shifted away from the initial presumption that immigration officers are bound by traditional Fourth Amendment requirements. In so doing, it has made distinctions among various classes of persons to determine whether the Fourth Amendment applies to them. The Court has given considerable latitude to immigration law enforcement officers, even as it has refused to abandon explicitly the requirement that searches and seizures must be individualized under some circumstances.

Immigration Aspects of Other U.S. Legislation

Two important U.S. laws enacted in 1996, other than IIRIRA have significant provisions relating to immigrants. The first of these is the welfare law (the Personal Responsibility and Work Opportunity Reconciliation Act of 1996), and the second the Anti-terrorism and Effective Death Penalty Act of 1996 (AEDPA). In addition, the appropriations process has an important influence on immigration matters. Most immigration matters are within the purview of the two judiciary committees in the House of Representatives and the Senate, but the budget and appropriation committees of the two houses have great influence. Related legislation, even if it contains immigration provisions, comes under the primary purview

of the relevant committee for that subject, such as the House Ways and Means Committee for welfare matters.

Under the welfare bill, illegal immigrants are ineligible for most public benefits. For the most part, this was the case before the legislation. Illegal aliens remain eligible for emergency Medicaid, school breakfast and lunch programs, soup kitchens, public health assistance for immunizations, disaster relief, and certain housing benefits if receiving them on the date of enactment of the legislation.

More to the point, therefore, because the prohibitions are new, are those directed against legal immigrants. They are barred from receiving Supplemental Security Income (SSI), food stamps, and Medicaid until citizenship or until the immigrant has worked 40 qualifying quarters and did not receive any Federal means-tested program during any such quarter. There is an exception for refugees, asylees, and individuals granted withholding of deportation during their first five years in the country and for veterans and active duty service personnel. States have authority to determine eligibility for Aid to Families with Dependent Children and state welfare programs. The immigration legislation amended the welfare law to permit battered women to receive public benefits under certain circumstances.

Legal immigrants will be subject to deeming rules in determining eligibility for federal programs until citizenship or until the immigrant has worked 40 qualifying quarters and did not receive any Federal means-tested program during any such quarter. This means that affidavits of support signed by those who sponsor immigrants for admission are legally enforceable. States have the authority to limit eligibility or to deem sponsor income and assets, with similar exceptions.

Governor Wilson, who had been prevented by the courts from implementing many of the provisions of Proposition 187, used the provisions of the welfare legislation to accomplish many of the same objectives. Less than a week after the welfare bill became law, he issued an executive order to state agencies and state-supported universities to cut off benefits to illegal aliens.

When he signed the welfare legislation, President Clinton stated he would try subsequently to soften the impact on noncitizen legal residents. The Republican chairman of the House Ways and Means Committee, Bill Archer of Texas, was quoted as saying that if the president wants to undermine and weaken the bill by allowing noncitizens to receive welfare payments, "I will fight to protect the taxpayer."[44] Nevertheless, some restitution of benefits was included in the 1997 legislation to reduce taxes and balance the federal budget by the year 2002. Restoring full benefits to noncitizen legal residents would require finding an estimated $20 billion elsewhere in the budget, either by reducing other programs or raising new revenue, and this is therefore unlikely.

The AEDPA of 1996 was enacted to take effect in April 1997 and it provides the basis for expedited deportation of persons considered criminal aliens. It

prohibits the Attorney General from releasing from custody any criminal alien deportable for having been convicted of either two crimes involving moral turpitude within five years of entry, a firearms offense, a drug offense, and aggravated felony, or a security-related crime. In earlier legislation, the Board of Immigration Appeals could suspend forced removal of an alien who has become acclimated to the United States on the grounds that this would inflict great hardship, but under the AEDPA hardship will no longer be a criterion for suspending forced removal. The definition of aggravated felony was expanded in the AEDPA to include, among other offenses, theft or receipt of stolen property for which the term of imprisonment is five years; and forgery, counterfeiting, mutilating, or altering a passport in violation of the Immigration and Nationality fraud provisions for which an 18-month sentence is imposed.

Like the IIRIRA discussed previously, AEDPA precludes judicial review of administrative decisions, such as final orders of deportation of most criminal aliens and places strict limits on issues to be considered in a *habeas corpus* review. This removes many critical legal safeguards available to citizens.

When provisions on immigration and treatment of immigrants, those in the United States legally and illegally, and on refugees and asylees, are scattered in many bills, inconsistencies and anomalies are sure to arise. This is particularly true when compromises on complex legislation are reached at the 11th hour, as was the case for the immigration and welfare laws. This is why a bill to deal with technical corrections was necessary in the new Congress. The more widely spread across many laws are provisions dealing with immigration, the more complex it becomes to make changes. The technical bill was vetted across the government in the Departments of Agriculture, Education, Health and Human Services, Labor, Justice, and the Social Security Administration. Such legislation often goes beyond technicalities.

Interplay between Federal and State Actions in the United States

Control of borders is a federal responsibility, a fact that contributed to the delay in implementing the legislation that grew out of Proposition 187. However, once in the United States, the bulk of the impact of immigration falls on those places where the immigrants live, the states and localities. Most public services that are provided are done at the expense of the states and localities. Because the impacts differ among the states, there is no single view on such issues as welfare, education, health care, or even on attitudes toward welcoming or resisting immigrants. The differences among the states may become even more sharp in the future now that many welfare decisions are being decentralized.

The proposed Gallegly amendment on education brought out these differences quite vividly. Representative Gallegly, a Republican, is from California and his proposal to deny education to illegal alien children probably represented the majority view in that state. Senators Gramm and Hutchison, both Republicans from Texas, represented a different viewpoint, one shared by that state's governor, George W. Bush, also a Republican. The speaker of the House of Representatives, Republican Newt Gingrich supported Gallegly. He phrased his position as follows: "California decided by statewide referendum not to pay for these benefits; this should be its right. Texas, on the other hand, has chosen to pay for these benefits; this also should be its right."[45] The Texas position was not always thus, of course. The leading U.S. Supreme Court decision requiring the education of illegal alien children, *Plyler v. Doe*, grew out of a case brought against a Texas law of 1975 denying such education.

A number of states have brought suit to recover costs they must bear for providing services to illegal aliens, all unsuccessful thus far. In their letter of opposition to the Gallegly amendment, Senators Gramm and Hutchison stated their support for federal funding of these education costs. A disproportionate share of these education costs fall on seven states: California, New York, Florida, Illinois, Texas, New Jersey and Arizona.

The Republican Mayor of New York City, Rudolph Giuliani, has argued against welfare cuts for most legal aliens. He cited data showing that recent legal immigrants use public assistance less than native New Yorkers (11.2 versus 13.8 percent), which is the reverse of the data cited by California. A proposal to deny public services to illegal immigrants was killed in Florida in April 1995 based on opposition from Cuban-American legislators. Instead, a commission was established to study the issue.[46]

When Proposition 187 passed in California, there were predictions that the sentiment embodied in this referendum would sweep across the country. There were echoes of support in other states and at the federal level, but there also were manifestations of opposition to this approach. The variety of state and locality responses is a reflection of many distinct circumstances across the nation. Some of these disparities are different economic situations among states and localities, unique ethnic mixes, varying power relationships between Latinos and others, and non-uniform perceptions of self-interest.

Nationals and Foreigners in Mexico

Immigration issues and immigration legislation have a radically different significance in Mexico than they do in the United States. Mexico does not view itself as a country of immigration. Immigrants in 20th century Mexico have been

few in number and of marginal demographic significance. On a few occasions, however, Mexico opened its doors to immigrants. This took place at the time of the Spanish Civil War, before and during World War II, and in the 1970s and 1980s for South and Central Americans. The 1990 census showed that less than 0.5 percent of the national population is foreign-born, compared to 9 percent in the United States (in 1995). Though few in number, foreigners traditionally have come with capital and skills to Mexico, and therefore have had a salutory impact on the country's economy disproportionate to their number.

The Mexican Revolution of 1910 was in part a negative reaction to the enormous concentration of land, industry and wealth in Mexico in the hands of a small number of persons, many of them foreigners. The Constitution of 1917 and the legislation adopted in later years reflected these concerns. The new legislation curbed the property rights of foreigners. Mexico's foreign policy at that time began to promote the idea of noninterference in the domestic affairs of states and the doctrine that foreigners, as part of the condition of their admission, would have to renounce the right to appeal to their home governments for support beyond the rights already established under Mexican law.

Mexican legislation significantly curbed the right of foreigners to own real property, especially along the coasts and near international boundaries; made it difficult to naturalize; and established in the Constitution the right to deport foreigners for violations of Mexican law. Post-Revolution governments reversed the pre-1910 policy of encouraging foreign immigration. These governments also were disturbed by the growing emigration to the United States and the lack of population of certain parts of Mexico and began to encourage the repatriation of Mexican emigrants. The experiences of the late 19th and early 20th century turned Mexico away from the promotion of immigration and toward coping with the growing flow of nationals departing the country to the north.

Because Mexico is essentially a country of emigration of nationals rather than of immigration of foreigners, much of what is important in migration laws and policies relate to how nationality is defined and what are the rights of Mexican nationals while traveling and in the border regions.

Under Mexico's laws, all residents have freedom of movement within the territory. Like many other countries, Mexico has formal requirements for the entrance and departure of nationals and foreigners. (The United States, by contrast, does not have formal departure requirements.) However, in practice, many of these formal requirements are often ignored and are probably not enforceable, especially when departures take place away from designated exit points. In any case, the constitutional right to free transit has been interpreted to mean the right to leave the country, regardless of compliance with formal requirements. This interpretation has not been tested in the Mexican courts. This interpretation was modified during the

Bracero Program when the Mexican government made modest efforts to patrol its side of the border to prevent unauthorized departures and again when it briefly used armed force to prevent the unilateral recruitment of *braceros* by the United States. The Mexican national consensus since the modest efforts during the Bracero Program has been that the Constitution prevents the government from stopping the departure of nationals from its territory.

In December 1996, Congress passed constitutional amendments often referred to as "dual nationality," whereby Mexicans who take another nationality at the time of foreign naturalization do not automatically lose their Mexican nationality and citizenship. As a result, once the amendments become effective, Mexican-born persons naturalized as citizens of another country will no longer be treated as foreigners upon their return to Mexico and their property rights and other rights will not suffer. (See Volume 3, pages 1249 to 1250, on the unrenouncability of the Mexican nationality).

Immigration Law in Mexico

Mexico's immigration law traditionally has been enacted within the framework of what is termed "population law," which includes policies designed to influence population dynamics, the promotion of settlement of sparsely populated areas, and the distribution of Mexico's resident population. Immigration is thus an aspect of population policy and this approach underscores the view that Mexico is more concerned with population growth and distribution than with the admission of foreigners.

The current population law in Mexico dates from 1974, but this law has been amended on several occasions, most recently in 1990, 1992 and 1996, to liberalize the entry of certain categories of foreigners and to strengthen the penalties against those who traffic in migrants.

A feature of Mexican immigration policy is that it gives priority to foreign applicants who have needed skills from the standpoint of Mexico's economic development. Mexico is a country with a shortage of certain kinds of skilled workers, and although immigration policy has not encouraged the *recruitment* of such workers, it has given priority to their admission. In many instances, skilled immigrant workers are required to certify that they will participate in the training of domestic workers who wish to acquire these skills.

Another feature of Mexican immigration policy, and perhaps the most important, is that the legislation indicates goals and priorities without specifying the number or proportion of immigrants to be admitted under each category. Indeed, Mexican immigration law gives great administrative discretion to the executive branch to decide on a case-by-case basis whether particular decisions are consistent with the overall policy goals.

Like the United States, Mexico assigns a high priority to the admission of the immediate relatives of Mexican nationals and resident immigrants. It appears that the majority of the relatively small number of immigrants (*inmigrantes e inmigrados*) admitted each year are essentially based on family reasons.

Immigration policy and practice has undergone subtle but important changes since about 1980. The impetus for change came with the mass movement of Central Americans into Mexico, especially near the southern border. Suddenly, Mexico seemed to be not just a country of mass emigration, but also of substantial immigration—at least of asylum seekers. Moreover, Mexico experienced the new situation of many foreigners entering illegally in order to proceed to the United States. Mexico, therefore, modified its legislation and administrative procedures to deal with these new circumstances by creating the category (*calidad*) of refugee (1990) and increasing penalties for illegal trafficking in migrants in and out the country (1990 and 1996).

Another event which provided stimulus for modifying immigration legislation was the need to accommodate to the mobility of an open economy (and of NAFTA), the influx of investment, and the provision of services. Mexican law was modified (1992) to facilitate the entry of business visitors, investors, technicians, professionals, and others to conduct business in Mexico. Special facilities are given to American and Canadian businesspersons to enter Mexico. In the year April 1994 to April 1995, the number of U.S. and Canadian businesspersons entering the country on a temporary basis (FMN) was a little more than 47,000, more than 95 percent U.S. citizens.

Professionalization of Immigration Administration in Mexico

The new circumstances of the past decade and a half, and the parallel decision of the Mexican government to engage the United States more actively in migration matters, have contributed to the increasing professionalization of the administration of Mexican immigration policy. In 1993, the National Institute of Migration was created. One of the main objectives of current migration policy is to improve the services required by immigrants by simplifying regulations and procedures, upgrading the quality of personnel, and strengthening the administration, and the fostering a culture of service and probity.[47] Thus, the Secretaría de Gobernación, together with the National Commission for Human Rights, has issued a brochure designed to prevent the violation of human rights of migrants (*Cartilla. Guía de Derechos Humanos para Migrantes)*. Indeed, it is safe to assume that in shaping migratory behavior, Mexican authorities have in

mind the probability of comparisons between what Mexico demands for its citizens and the way Mexico treats its immigrants, be they authorized or unauthorized.

Other Actions to Encourage or Discourage Migration

Mexico

Discourage Migration: An Elusive Ambition

As a matter of principle, Mexico has not taken any action to encourage migration. On the contrary, a traditional position is that emigration of nationals is a loss to the country. Therefore, through the years, some actions can be listed that had the purpose of discouraging migration. (Usually this is not the only, nor the most important, purpose.) Most of these actions relate to the promotion of economic development. It is commonly accepted that development is the best, and only, long-term deterrent of mass emigration. All developmental actions are obviously not related to migration. What it means is that since 1965 there have been developmental measures whose goals included keeping would-be emigrants within the national territory. This migratory consideration usually is a minor or indirect one. Migration might play the role of safety valve, but not by design.

The Border Industrialization Program

This program, also known as the *maquiladora* program, encourages the establishment of in-bond plants to assemble imported components from the United States to be then exported back. The program was established in 1965 precisely after the termination of the Bracero Program with the intent of absorbing would-be migrants. At the start, this program probably absorbed some local population. The role of this program regarding the dynamics of Mexican migration to the United States is a question that continues to be matter of debate. In any event, the *maquiladora* program employed around three quarters of a million workers at the end of 1996.

Economic Development in Origin Regions

After Mexico stopped seeking a renewal of a Bracero Program in the mid-1970s, influential Mexican analysts proposed the establishment of special economic development programs precisely in regions of origin of the migrants. The purpose of these proposals was to keep people in their places of origin.[48] The hope was to obtain additional or special resources (from the outside) to be channeled to

the emigration regions. These proposals never prospered. However, they show a continuity in the Mexican attempts to discourage emigration.

NAFTA

One major action undertaken to discourage migration is NAFTA. Of course, migration was not an overriding consideration to negotiate NAFTA. However, the argument can be made that migratory considerations played a role in strengthening the case for NAFTA. NAFTA is a development strategy that has a built-in, indirect migratory effect—that price (wage) equalization would, eventually, discourage emigration. This potential migratory effect—even if long term—was useful in "selling" NAFTA.[49] NAFTA has provisions (chapter 16) to facilitate the mobility of technical and business persons, but they are based on a different perspective. This mobility is seen as associated or attached to the increased mobility of capital, services and technology transfers.

United States

Worksite Verifications

The 1996 immigration legislation establishes three separate pilot programs to confirm employment eligibility. Each has a duration of four years and is to be conducted within a year of enactment of the law in at least five of the seven states with the largest undocumented immigrant populations. Each program is voluntary for most private employers (but not for the executive and legislative branches of the federal government), but mandatory for job applicants.

The first, the basic pilot program, requires new employees to provide their Social Security numbers and, for non-U.S. citizens, INS identifying information. Employers are required within three days of hire to use a toll-free confirmation system to identify the employee's work eligibility. The second, called the citizen attestation pilot program, is permitted only in states where driver's licenses and identification cards have enhanced security features. This program is limited to 1,000 employers to be chosen by the Attorney General. The third, the machine readable document pilot program, is similar to the basic program except that the new employee presents a machine-readable Social Security number and the employer's inquiry is made through a confirmation system using the machine-readable feature of the document. Noncitizens must also provide their INS-issued numbers.

The ease with which documents could be forged was the Achilles' heel of the employer-penalty program under IRCA. The electronic verification pilots (or EVPs) could be significant ultimately in deterring employment of illegal aliens, but not in the short term. The new pilot programs are seen as an interim measure and depend

on self-certification by the alien. Thus, an alien with a valid Social Security number who claims to be a U.S. citizen will not be detected. The joint electronic verification pilot (JEVP) with the Social Security Administration was put on hold in the final immigration compromise.

The EVP is voluntary and, as of the end of February 1997, some 1,200 businesses were participating. They include meat packing in the midwest, poultry in the Delaware-Maryland-Virginia area and Georgia, and about 75 hotels in South Florida and San Diego. An interesting example among the volunteers is the Northwest Reforestation Contractors Association. Members of the Association claim that many reforestation contractors working for either private timber companies or the U.S. Forest Service and the Bureau of Land Management typically hire aliens illegally in the United States to perform the work, permitting them to underbid those contractors who do not, with no real danger of penalty even after IRCA. The group stated that it tried to work out something with the U.S. government, including the INS, in the years since IRCA, but with no concrete result. The problem was brought to the attention of the Commission on Immigration Reform, and from there to the INS, and the pilot program will include screening for unauthorized aliens on federal intensive-management contracts.

Nonimmigrant Visa Overstayers

The most recent INS estimate of the foreign population illegally in the United States (released February 7, 1997) was five million as of October 1996, and growing by 275,000 people per year. Of the five million, the INS estimate was that 2.9 plus million (59 percent) entered the United States without inspection, and 2.1 million (41 percent) overstayed. The INS estimate was that 2.7 million of the five million were Mexicans.

The INS response to reducing the population illegally in the United States must thus have two separate components, prevention of entry at or near the border and detection of people already in the United States either because they successfully evaded border deterrents or entered with valid visas and then abused the terms of their permission. Extensive investigation to locate the latter is not considered cost effective.

The INS makes a number of assumptions with respect to nonimmigrant visa overstayers. Its February 1997 report states that of the 25 million persons admitted as nonimmigrants in FY 1996, an estimated 98.5 percent will return home. The INS believes that many of those who do not when the term of the visa expires have a pattern of overstaying, returning home after a few years, and then repeating the process. Many, the INS believes, return to work in particular activities in specific locations, and increased inspections are to be conducted at these worksites.

More important, under new procedures, a part of the I-94 form that nonimmigrants must complete at entry will be stapled into the passport for surrender to the airline on departure. Depending on airline cooperation, this is intended to facilitate discovery of overstayers. By means of an on-line system with U.S. consulates, this information will be accessible when the person seeks a new visa. About 60 percent of countries now have machine-readable passports that can be checked at consulates. Armed with this information, the consular officer can than take appropriate action, from a warning, to a fine, to visa refusal. This, as of now, is the thinking about dealing with the visa overstayer problem.

The INS concern is not about overstays of a few days or a week, but rather a pattern of overstaying for a year or more. The system of notifying the INS of overstays using the returned portion of the I-94 form will be tested at five busy airports, with the cooperation of the airlines. This authority already exists in legislation. Depending on the results, the program can be expanded later.

Labor Department

The Wage and Hour Division of the U.S. Department of Labor has responsibility for enforcing a number of laws which establish standards for wages and working conditions designed to protect low-wage workers. All these laws deal indirectly with immigrant labor, and a number do so directly.

The Division's major task is to insure compliance with the Fair Labor Standards Act and this has implications for immigrant as well as national workers. The Migrant and Seasonal Agricultural Worker Protection Act provides for registration of farm labor contractors, proper maintenance and insurance for vehicles used to transport migrant and seasonal farm workers, maintenance of healthful housing and facilities for these workers, and prior disclosure to workers of employment conditions and agreements. Under IRCA, the Wage and Hour Division was charged with reviewing employer compliance with employment eligibility verification. The Division has authority to inspect employer compliance with worker protections under H-2A (temporary nonimmigrant agricultural workers), F-1 (foreign students), H-1B (foreign specialty workers), and D (foreign crew members doing longshore work) visa programs.

The Wage and Hour Division is working with the INS to coordinate enforcement activities, including inspections, in specific industries that have been found to violate immigration and labor laws (such as garment manufacture, janitorial services and agriculture) in seven targeted deterrence zones (in California, Texas, Arizona, New Jersey, New York, Florida and Illinois).

There are thus two lines of protection against hiring and/or exploiting workers illegally in the United States, the employer-penalty program initiated by IRCA,

and the enforcement efforts of the Labor Department which can uncover violations of wage-and-hour laws that affect immigrants as well as nationals. The two can work in tandem, as is now the practice in the targeted deterrence zones; but each program has its limitations. Those of the worker-penalty program under the aegis of the INS are discussed above.

The Wage and Hour Division is thinly staffed to carry out the tasks assigned to it. Its budget authority permitted a staff of 1,289 full-time equivalents in FY 1996, which is lower than in any year of the last five. Enforcement actions completed were lower in FY 1996 than in any of the last 10 years. This means that the Division cannot effectively carry out its responsibilities without substantial voluntary compliance. This need for voluntary compliance exists as well for the INS in its enforcement of the employer-penalty program, including the new electronic verification system pilot programs.

Reactions and Counter-Reactions

Cooperative Activities

The increased institutionalization of relations between Mexico and the United States in the last few years has facilitated cooperation on migration matters. The cooperation has dealt mainly with safety at the border, repatriation and education of immigration officials.

Cooperation dealing with safety at the border consists mostly of sharing information between various police and law enforcement agencies of the two countries, strengthening the links between Mexican consular officers in the United States, and prosecution of traffickers in migrants. The initiatives seek to achieve a safer border and a more ordered repatriation process, including procedures to forewarn authorities of the place and time of repatriation of undocumented immigrants at the border and to carry out an internal repatriation program. The education activities include the participation of Mexican officials in the Citizens Advisory Committees, mutual visits between INS and INM personnel, including the teaching of courses on Mexican culture by Mexican instructors to INS personnel and vice-versa.

Reactions to Unilateral Initiatives

Reactions to new initiatives can be quite important.

Increase in Naturalizations

A number of U.S. actions stimulated legal resident aliens from Mexico (and other countries) to naturalize. These actions already have been discussed. They include

Proposition 187, concern over what was seen as growing anti-immigrant sentiment in the United States, and the removal of many benefits to noncitizens under the welfare legislation. These measures led also to the conviction that the best way to combat future actions of this nature was through empowerment at the ballot box, and a necessary first step for this is U.S. citizenship. This reaction of Mexican Americans and other Latinos had considerable impact on the 1996 elections and can have even more profound implications for the direction of U.S. politics in the years to come.

More Mexicans were admitted as legal immigrants in the years 1970 through 1994 than any other nationality but, according to the INS, only 19 percent had naturalized. This was one of the lowest percentages of naturalizations of any country. In U.S. fiscal year 1993, which antedates the passage of Proposition 187, the number of Mexicans naturalized totaled 23,630. This figure jumped to 39,294 in FY 1994, then to 67,277 in FY 1995, and a verified minimum of 232,702 in FY 1996. The impulse to naturalize has not been confined to Mexicans; the total number of application in FY 1995 was under one-half million, which jumped to 1.3 million in FY 1996, and is projected to exceed 1.8 million in FY 1997. The earlier annual average was 300,000.[50]

INS Commissioner Doris Meissner has said she wished to activate the "N" in the Immigration and Naturalization Service. The INS, consequently, set up a procedure to reduce the time to no more than six months from application to naturalization. This goal has since slipped to nine months or more. In any event, the INS has been criticized for rushing naturalizations to influence the 1996 elections, a charge vehemently denied.

English Language Usage

The use of Spanish in the United States grew as Latin Americans constituted increasing proportions of legal immigration. During the 1980s, they represented almost half the legal immigrants, followed in numbers by Asians. Affirmative action programs, particularly under the stimulus of the Great Society in the 1960s, led to bilingual education programs. The U.S. Supreme Court, in *Lau v. Nichols*, ruled in 1974 that providing instruction only in English denied equal educational access to children who do not speak English well.

There has been a reaction to this on two grounds—fear that the preeminence of English in the United States would be diminished; and an opposite concern, that the children themselves would be disadvantaged by an inadequate ability to speak, read, and write English. Measures to designate English as the official language have been passed in 23 states, and may arise at the federal level.[51]

On December 4, 1996, the U.S. Supreme Court heard a case that arose from a constitutional amendment passed in Arizona in 1988 designating English as the official

state language and requiring government workers to conduct state business only in English. This was challenged by a state worker who often used Spanish in her job as an insurance claims manager. As the case proceeded, the amendment was struck down in the courts. Subsequently, the state employee who initiated the challenge left her job and state officials decided not to defend the measure. However, the group that had campaigned originally for the amendment, Arizonans for Official English, stepped in to defend it. At the Supreme Court hearing, several justices raised questions as to whether the case was moot, and in any event whether Arizonans for Official English had any standing. Justice Anthony Kennedy told the attorney for the Arizona group: "The voters didn't give any authority to you." The Supreme Court on March 3, 1997, unanimously threw out earlier judgments on the grounds that the case was moot when the employee left her job. The court also questioned whether Arizonans for Official English could act as agents for people of Arizona.

Mexican Constitutional Change Permitting Dual Nationality

As noted earlier, in December 1996, the Mexican Congress passed constitutional changes that would allow Mexicans to keep their Mexican nationality even though they opt for acquiring another. These changes took the form of making Mexican nationality unrenounceable, except in specified circumstances. This Mexican reaction complements earlier steps to provide information (although not encouragement) about the U.S. naturalization process.

The details of how dual nationality would work are still unclear. The key stated motive was to permit Mexicans who naturalize in the United States to retain property rights in Mexico. (See earlier discussion on the limits imposed on foreigners to own property in Mexico under the 1917 Constitution.) It is unclear whether the dual nationality would permit voting in Mexican elections. In practice, the decision on retaining Mexican nationality even as one naturalizes in another country is for Mexico to make. Mexico is not unique among countries that do not require, or do not recognize, renunciation of nationality; Great Britain, for example, does not recognize the giving up of allegiance by its nationals.

The Federation for American Immigration Reform (FAIR) criticized the Mexican action on the grounds that it would stimulate divided loyalties and undermine assimilation of Mexican immigrants. FAIR said it would seek legislation to annul U.S. citizenship of any person who exercises foreign citizenship.

Mexican Absentee Voting

The suggestion that Mexicans living outside the country be permitted to participate in Mexican elections via absentee voting raises less emotional issues than

those surrounding citizenship, but can lead to a negative reaction. The United States cannot object in principle to absentee voting since it is practiced in U.S. states. However, the sensitivity relates to the rallies and other campaign events at which the Mexican flag is shown prominently. An issue was made of this type of display by the group favoring Proposition 187 in California and this fact may have had some influence in the final outcome.

Yet, it is hard to argue that Mexican nationals living in the United States should be disenfranchised. The nub of this issue would seem to be the way absentee voting is handled, at least at the outset of the practice.

Mexican Use of Diplomatic Notes

In cases of incidents or specific actions, such as "Operation Hold the Line," a common Mexican reaction is the use of diplomatic notes, public protests or calls for consultation. In many instances this is the end of the affair, without a reversal of the triggering action. But in other instances, a process with cooperative ingredients follows.

The Changing Relationship

Relations between the Mexican and U.S. governments underwent a watershed during the 1989-1993 period. This relationship evolved from a non-engagement approach to a cooperative problem-solving problem attitude. For the first time in the history of the bilateral relationship, both federal governments began to foster and facilitate economic integration instead of repressing it. For Mexico, this represented a departure from the traditional defensive attitude, and the recognition of economic interdependence; and for the United States it represented a less confrontational stance with its southern neighbor.

During the administrations of Carlos Salinas and George Bush, the two governments devoted an extraordinary amount of attention to each other and sought to institutionalize their inter-governmental affairs. The process of institutionalization involved an increase in governmental contacts, the development of new rules governing U.S.-Mexico bilateral relations, and the creation of more effective consultative mechanisms. The empirical evidence that demonstrates this process of institutionalization is indeed impressive. The number of officials involved in the bilateral relationship increased dramatically. Almost every executive agency was drawn into the relationship. The linkages between U.S. and Mexican governmental agencies grew stronger and more direct; and contact between the agencies was increasingly conducted independently of the State Department and the Foreign Affairs Ministry in Mexico. Numerous cooperative and inter-institutional agreements were signed, creating various official working groups and bilateral commissions, which were

developed to support increased consultation. NAFTA alone has led to the creation of 22 committees and working groups.

This formalization of the bilateral dialogue and consultation has also permeated the migration agenda. During the last five years, there has been an upsurge of mechanisms for dealing with the complicated immigration flow coming from Mexico. The Working Group on Migration and Consular Affairs of the Binational Commission exemplifies this tendency to formalize consultation. The Group was created in 1987 as part of the Binational Commission. In 1992, it began to meet independently of the Commission, and during the past two years has met eight times. The highest level officials dealing with migration affairs participate in the Group: the INS Commissioner, the Assistant Secretary for Inter-American Affairs at the State Department, and the Mexican Undersecretaries of Migration at the Interior Ministry, and Bilateral Affairs at the Foreign Ministry, as well as more than 20 officials from the two countries. The Group has become a useful mechanism for bilateral dialogue and for coordinated efforts between the officials of both countries. The proposal for this Binational Study was formalized at the first meeting of the Working Group on Migration and Consular Affairs in Zacatecas, Mexico, in February 1995.

Other examples of this trend toward the formalization of bilateral consultation are the Border Liaison Mechanisms which, during the last three years, have included Mexican participation in the Citizen's Advisory Panel, and the Mechanism of Consultation on the Activities of the INS and Consular Protection, created in 1996. In May, 1996, Secretary of Foreign Affairs José Angel Gurría, and Secretary of State Warren Christopher signed a Memorandum of Understanding dealing with the protection of the rights of Mexican nationals in the United States. The MOU states seven principles and goals: First, to permanently include in the agenda of the Bilateral Working Group on Migration and Consular Affairs of the Binational Commission issues dealing with consular protection and human rights. Second, to notify any individual detained by migration authorities of his/her rights and legal alternatives, including the right to establish contact with his/her consular representative. Third, to facilitate communication between consular representatives and detained individuals. Fourth, to facilitate the presence of consular officials in judicial proceedings. Fifth, to bring to the attention of the Working Group on Migration and Consular Affairs reports on human rights written by the Border Liaison Mechanism, and the Mechanism of Consultation on the Activities of the INS and Consular Protection. Sixth, to promote transcultural understanding. Seventh, to promote high-level cooperation to facilitate the investigation of violent incidents related to consular protection.

Mexico has experienced profound changes in its economic and political structure during the past 15 years and these have affected relations with the United States.

These attitudinal changes in Mexico had a significant impact on U.S. thinking as well, drawing the United States closer to Mexico in its policies. These changes are also visible in the Joint Statement on Immigration signed by the two Presidents in May 1997. All is not sweetness and light, as the March 1997 drug certification conflict demonstrated, but even there a compromise acceptable to both nations was worked out.

NAFTA and Institutional Building

The changes in the Mexico-U.S. relationship during the past decade and a half have been breathtaking. The most important change is the entry into force of NAFTA on January 1, 1994. Regardless of one's opinion on the desirability of NAFTA, it is clearly an important agreement, probably the most important between the two countries in this century. Its significance transcends economic integration as such, as important as this is, because it forces greater cooperation than had existed earlier on other matters as well.

Mexico and the United States, as the title of Alan Riding's book put it, were "distant neighbors" for many years.[52] Mexican foreign policy emphasized independence from the United States. This showed up in secondary ways, such as opposing U.S. initiatives in international organizations; Mexico voted consistently in opposition to the United States in the United Nations General Assembly. On more profound matters, such as limiting foreign direct investment, Mexican policy was designed primarily to favor nationals over foreigners, but also to limit U.S. influence. The goods and services excluded under Mexico's import-substitution policy, to the extent that imports were less than they might otherwise have been, were primarily from the United States.[53] This also meant that Mexico exported less of its goods to the United States than it later did under a policy that emphasized more competitive industry.

Mexico, before the unilateral tariff reductions made prior to NAFTA, exported few manufactured goods. Today, manufactures dominate Mexico's exports. Mexico looked within the country for its economic growth before the changes that began in the 1980s. The domestic market is still more important than the export market, but not as overwhelmingly as before. Mexico's macroeconomic economic recovery in 1996 was largely export-led. About 80 percent of Mexico's exports now go to the United States. Merchandise exports are now equal to about 30 percent of GDP, which means that exports to the United States now represent some 25 percent of GDP.

The majority of manufactured exports are intra-industry in nature, and much of this is intra-firm. Increasing amounts of total trade are in intermediate products which serve as inputs for further production in the other country. The intra-firm

trade is evidence of much co-production, of parts produced in one country for assembly or further processing in the other.

NAFTA represented a conscious policy by Mexico to take advantage of the large U.S. market next door. It was predicated also on the desire to attract foreign direct investment, and traditionally two-thirds of this came from the United States. The cooperative economic relationship could not succeed unless the political relationship also became closer, and this has occurred. This does not mean that all differences have been eliminated, but rather that differences are not sought out for their own sake.

These changes in economic relations and political interactions are likely to become more solid with the passage of time and the entrenchment of vested interests in production and trade in the two countries. Durability depends also on the construction of institutions and these have flourished since NAFTA. As noted above, the once formal intergovernmental relations have become more flexible. The Mexican authorities now lobby in the United States, which they did not prior to the NAFTA negotiating process. The Mexican government no longer operates solely via its Secretariat for Foreign Relations (SRE) communicating with the State Department, but rather across the spectrum of U.S. public and private agencies and the Congress. On migration, it is worth noting the participation of the Secretariat for Government Affairs (Gobernación). Counterparts from the two countries communicate directly by telephone, fax, and e-mail, when earlier everything went through the SRE.

This greater intimacy permits easier communication on most subjects, from drug trafficking to labor and environmental relations. Increased dialogue on immigration matters also stems from a combination of this new institutional flourishing and the Mexican concern over the anti-immigrant sentiment reflected in Proposition 187, and the expectation that the United States was becoming more serious in preventing entry over the border without documents. The principal fruits of this dialogue have been greater attention on protecting the rights of Mexicans, legal and otherwise in the United States.

The increased closeness of the economic relationship and its salience for Mexican economic recovery and growth also meant that it became important to handle other problems in a way that avoids prejudice to economic cooperation. This was one basis of the shift from political distancing to greater dialogue. It has also meant that when migration incidents flare up, as they did in Riverside County in 1996, the Mexican authorities prefer to handle these calmly. The Mexican media reacted—overreacted—harshly to the two incidents in Riverside County, but the government sought correctives. The language used domestically to calm the political furor was stronger than the action taken bilaterally with the United States, which was designed to find satisfactory solutions looking to the future.

The greater intimacy has not eliminated all conflict. Trade disputes still arise—as one would expect from increased trade. The contentious issue of certifying Mexico for cooperating with the United States to combat drug trafficking which President Clinton did as of March 1, 1997, brought out long simmering differences and this issue has the potential of limiting cooperation between the two countries on other issues as well. There is still considerable opposition to NAFTA in both countries, and this could lead to serious misunderstandings. History has not been erased by recent bilateral interactions, but a cooperative layer has been superimposed on old mistrusts.

Immigration Provisions of NAFTA

Immigration is not dealt with in NAFTA except for temporary business visitors, but the relationships spawned by the agreement have their effects on the bilateral immigration relationship. This binational report would not have been possible in the pre-NAFTA period, but it is not remarkable today. The immigration relationship is not a rose garden—the asymmetry makes this impossible for now—but the dialogue is civilized.

Chapter 16 of NAFTA permits the entry into each of the three member countries of business persons and technicians from the other two. For the United States, this temporary entry extends to a number of categories of business visitors (B-1); traders (E-1); investors (E-2); intracompany transferees (L-1); and professionals (TN). The TN category (Trade NAFTA) is available only for citizens of Canada and Mexico who meet certain educational and experience requirements. A TN visa is issued for one year and there are no limits on the number of allowable extensions.

A transitional annual limit of 5,500 was established for Mexican professionals who can enter the United States under the TN category. There is no limit on Canadian TN professionals. The limit can be increased by mutual agreement between Mexico and the United States and will expire in 2003, unless the two countries agree to eliminate it earlier. Canadian TN professionals remain exempt from the TN visa requirement (that is, they can show up for admission and be admitted), whereas Mexicans must first obtain a visa. The reason for the disparate treatment of Mexicans and Canadians apparently was based on lesser experience with Mexican TN professionals and the desire to let the number build up on a gradual basis. If need be, Mexican professionals can still enter under the H-1B category, for which there is a worldwide limit of 65,000, if this limit has not been breached. Mexico has tried, without success thus far, to get a freer regime, including permits for those accompanying the business persons admitted to the United States under NAFTA chapter 16.

Tension between Free Trade and Immigration Restrictions

The current situation is that goods and services can pass more or less freely across the Mexican-U.S. border, as can capital, but not labor. The reminder is needed that NAFTA is a free-trade area and not a common market within which all factors can move freely. Mexico, in the buildup to the NAFTA negotiations, raised the issue of labor inclusion more broadly than in chapter 16, but this was rejected by the United States on the grounds that this would not be accepted by the Congress.

Does the disparate treatment of goods, services, and capital, as distinct from labor, augment the tension that exists in any event on the immigration issue? The argument that it does is made on the theoretical ground that if one factor (capital) can move freely, then the other (labor) should be able to do so as well. This, however, may be more of a debating point than a solid argument. People are different from capital, even if one can partially substitute for the other. Trade can also be a partial substitute for the movement of people.

The argument that the tension on immigration is not heightened by NAFTA is that free movement of goods, services, and capital can ease the pressure on labor migration, at least over time.

In any event, the idea of completely free movement of people between the two countries is moot, certainly for now. There are proposals from time to time for a guest-worker program with Mexico for the admission of less-skilled workers; a modest one exists between Canada and Mexico. Such proposals are motivated not by the theoretical argument for equal treatment of all factors, but rather the inability of Mexico to control emigration and of the United States to completely seal the border.

Conclusions

The basis for each conclusion is contained in the previous discussion.

Episodic Nature of U.S. Responses

Responses to curtail unauthorized immigration are episodic, most intense when the U.S. economy, or the economy of California because of its importance as an immigrant-receiving state, or the economy of Mexico, falters. Historically, the intensity of the anti-immigrant effort has diminished as economic conditions improved. This suggests that changes in immigration practices may be more feasible when the two economies are prospering and tensions are minimal.

Official Action and Effectiveness of Immigration-Restriction in Practice

In the past, official U.S. responses to deal with the inflow of unauthorized immigrants were consciously riddled with loopholes or not carried out with vigor. The Texas Proviso was the classic example of this. More recently, the employer-penalty provisions of IRCA were compromised at the outset by failure to have an effective way to identify persons entitled to work in the United States, and then further weakened by lax enforcement. It remains to be seen whether the current efforts to deter illegal immigration will be more durable than in the past and if they will be pursued more vigorously.

Mexican Engagement

One new element for dealing with the illegal-immigrant inflow into the United States is the shift in the Mexican position from a "no-policy" policy, or deliberate non-engagement, to a stance of increasing engagement with U.S. counterparts. The ultimate effect of this engagement is hard to forecast because the Mexican priority is to protect the rights of its nationals in the United States, while that of the United States is for the Mexican authorities to actively deter the unauthorized movement of persons. Each side has responded to some extent to the priorities of the other. The U.S.-Mexico Memorandum of Understanding of May 1996 provides improved assurance of humane treatment of Mexican migrants in the United States; and Mexican legislation to more severely punish nationals who traffic in unauthorized migrant movement has a direct deterrent motive. However, these actions, as useful as they are symbolically, are unlikely to have much effect on unauthorized migrant movement over the border.

Greater Role for State and Local Authorities

Because immigration is a federal responsibility in both countries, most bilateral discussion takes place at this level. However, the impacts of migration are felt primarily at state and local levels. In addition, many of the issues affected by migration, such as welfare in the United States and education in Mexico, are being devolved increasingly to state and local levels. State border governors from the two countries meet regularly. These considerations lead to the conclusion that it may be useful to bring state and local authorities more actively into bilateral immigration discussions.

The Role of Nongovernmental Organizations

These groups have increased their activity. Proposition 187 was stimulated by an NGO initiative, although it obviously received considerable official stimulus from the support of Pete Wilson, the governor of California. The constitutional case against Proposition 187 was led by the American Civil Liberties Union. Many U.S. NGOs were involved in the debate on welfare and immigration legislation. Mexican NGOs pressed their government to be more vigorous in protecting human rights of Mexican nationals in the United States.

Interplay between Economic Integration/ Political Cooperation and Immigration Control

The negotiations for and then the entry into effect of NAFTA changed the context of Mexican-U.S. relations. What earlier had been a distant relationship, with few institutionalized links, was transformed into a bilateral partnership replete with public and private institutional contacts. NAFTA also forced a more cooperative political relationship in order to avoid contamination of the increased economic interaction by political disputes.

The recent trend towards the institutionalization of relations between the Mexican and the U.S. governments has also permeated the migration issue area. In the last five years, there has been an upsurge of initiatives to formalize the bilateral dialogue and consultation on migration between Mexican and U.S. officials. It is still early to assess the effectiveness of this bilateralism for preventing or solving migration disputes. It is noteworthy, nevertheless, that this trend occurred in a period of intense immigration debate in the United States, and when the mood of the nation has apparently become less receptive to immigrants.

While the bilateral engagement on migration issues began before NAFTA went into effect, cooperation on this issue also picked up after NAFTA. Mexico's decision to engage in dialogue on migration matters is likely to increase the pressure on its government to become more active in the day-to-day administration of these issues.

Border Opening for Commerce and Investment But Not People

Because of NAFTA, the importance of the U.S.-Mexican border is diminishing for the flow of goods, services, and capital. In addition, measures have been taken by the United States to facilitate legal human flows across the border. By contrast, the United States simultaneously is increasing its efforts to control unauthorized

entry across the border. This has the potential for increasing binational tensions, as highly publicized incidents of the effects of this greater surveillance occur, such as those in Riverside County, California, in 1996. This tension between opening for commerce and investment and closing for unauthorized border crossing is unlikely to disappear in the near future and the policy task is to minimize the inherent friction.

Human Rights Protection

The Mexican government continues to emphasize a traditional preoccupation with violations of the human rights of its nationals in the United States, particularly when instances of violence associated with the activities of U.S. law enforcement bodies come to light. Successive Mexican administrations have strengthened the network of consulates in the United States and have made these the forward arm of policy to protect the human rights of Mexican nationals. At the federal level, the U.S. government has been more sensitive to the Mexican demands for human rights protection. Much of the increased binational dialogue on migration issues deals with this theme.

Sensitivity Training

Violations of the human rights of Mexicans in the United States are likely to receive much media attention in Mexico and damage the bilateral relationship. Sensitivity training of U.S. immigration and police officials to minimize such incidents is thus a good investment.

Immigrant Access to Social Services

Recent political trends in the United States have been running in the direction of excluding immigrants, authorized or not, from receiving tax-supported social services. Examples of this tendency include Proposition 187 and provisions of both the welfare and immigration legislation of 1996. Proposition 187, because it was seen in Mexico as being directed against Mexican nationals, led to considerable tension between federal officials in Mexico and state officials in California. Internally, in the United States, what were seen as anti-immigrant actions and curtailment of benefits to legal, noncitizen residents have led to increased naturalizations and political organizing among legal residents, Mexican and otherwise.

Unintended Consequences

Unintended consequences of legislation and other actions on immigration are legion. Perhaps the best example of this was the 1965 immigration act, whose

main purpose was to abolish the national-origins quotas and the Asia-Pacific Triangle, but not to radically alter immigration volumes and patterns. The law, in fact, did bring about a fundamental shift in immigration patterns in favor of family unification, led to the dominance of Latin Americans and Asians in U.S. legal immigration, and, because of the generous subsequent response to the post-1965 refugee crisis, resulted in a substantial increase in immigrant numbers.[54]

Termination of the Bracero Program in 1964 stimulated Mexico's border industrialization program and, over time, attracted many people to Mexico's northern border and, presumably, increased the ability to emigrate to the United States. The legalization provisions of IRCA have led to many immigrant applications for family reunification and have complicated dealing with the backlog of legal immigrant cases. Termination of many welfare benefits to legal immigrants stimulated the pace of naturalizations and voter registrations, which altered the outcomes of a number of political contests in 1996 in favor of Democratic candidates and may determine the political alignment of many Mexican Americans in the future. Making undocumented border crossing more difficult could lead many who succeed in making it across to stay put in the United States rather than return to Mexico after they complete seasonal jobs.

Notes

*The work of this group was greatly facilitated by the support it received both from the staff of the U.S. Commission on Immigration Reform, including Susan Martin, Lindsay Lowell, Deborah Meyers, and especially Paul Donnelly, who spent considerable time researching the details of many issues important to our analysis and from the Mexican Coordination, including Enrique Loaeza and Romedios Gomez. Peter Hendricks searched the records and provided background information on immigration legislation, advocacy groups, public opinion polls and other matters. Georgina Rojas, who was a diligent research assistant, Laura Rubio and Monica Verea Campos have the gratitude of the two Mexican members of the team. The U.S. members of the team were greatly assisted by Lillian Tabe, Ellen Mansour, Lisa Cotter, and Suzanne Soule. This paper could never have been put together without the dedicated support of Carolyn Blackwell of the Center for Strategic and International Studies who kept the master copy of the group's writings and made literally hundreds of changes as our work proceeded.

1. Wade Graham, "Masters of the Game," *Harper's*, July 1996, pp. 35-50, makes this point quite forcefully. His point is that "illegal immigration is only epiphenomenally a law-enforcement issue; it is at root a labor-market event."

2. An examination of the data on the number immigrants admitted from Mexico and their departure from the U.S. suggests that about 650,000 legal immigrants from Mexico resided in the United States at that time. The 1930 census count of Mexican-origin population seems to have misclassified many Mexican-born as U.S.-born of Mexican origin, and that the total resident immigrant population may have been about one million.

3. The return flow was as high as 600,000 if the peak Mexican- born resident population was one million in 1930; the 1940 U.S. census reported slightly more than 400,000 persons born in Mexico. The net return flow to Mexico during the 1930s was greater than the net immigration to the United States in the 1920s if the census undercount of the Mexican-born in 1940 was not greater than the undercount of the 1920s, in that the Mexican- born population recorded in 1920 exceeded the 1940 count by several tens of thousands.

4. The Chinese Exclusion Act, adopted in 1882 for ten years, extended in 1892 and made permanent in 1902, was interpreted by the Chinese government as a badge of inferiority and created significant bilateral problems in U.S.-Chinese relations. The Act was repealed in 1943 at the express request of the Chinese government at a time when it was a wartime ally. Japanese immigration became controversial in the U.S. at about the turn of the century and in 1908 a "Gentlemen's Agreement" was negotiated under which the Empire of Japan agreed to not issue passports to those nationals who indicated their intention to migrate to the United States. The United States also adopted legislation making the Japanese ineligible for naturalization. The Gentlemen's Agreement failed to prevent Japanese immigration. In 1924 Congress extended the exclusion to those nationals ineligible for citizenship—a transparent decision to bar Japanese immigrants, and an action which created far more tension in U.S.-Japanese relations than had been expected.

5. Lawrence Cardoso, *Mexican Emigration to the United States*, 117.

6. Rodolfo de la Garza and Gabriel Szekely, "Policy, Politics and Emigration: Reexamining the Mexican Experience," in Frank Bean, et. al., *At the Crossroads: Mexico and U.S. Immigration Policy,* (Lanham, MD: Rowman and Littlefield, 1997).

7. Manuel García y Griego, "Hacia una nueva visión del problema de los indocumentados en Estados Unidos" in Manuel García y Griego and Mónica Verea Campos, *México y Estados Unidos frente a la migración de indocumentados* (México: UNAM-Porrúa, 1988) 123-152.

8. The Bilateral Commission meets once a year to discuss issues at the most senior levels. Seventeen cabinet members from the two countries participated in 1996.

9. Foreign Policy Association, National Opinion Ballot Report 1996. The other most important issue concerns were NAFTA and trade relations 26 percent, drug trafficking 22 percent, and political reform 17 percent.

10. Senado de la República, *Diario de los Debates*, Año I, Período Ordinario, LIII Legislatura, Tomo I, Núm. 28, December 4, 1985, pp. 4-15.

12. Carlos Rico, "Migration and U.S.-Mexican Relations 1966-1986" in Christopher Mitchell, *Western Hemisphere Immigration and United States Foreign Policy* (University Park, PA: Pennsylvania State University Press, 1992) 221-283.

13. A review of the Mexican press around 1994-1995 notes that the idea of exploring and establishing a *bracero*-type agreement has gained a wide consensus (amplio grado de consenso), Mónica Verea Campos, *La Propuesta 187: el debate en México*, CISAN, UNAM, January 22, 1997, p. 90 [Commissioned Paper].

14. In line with this objective, the Instituto Nacional de Migración, the Consejo Nacional de Población (both within the Secretaría de Gobernación), and the Instituto Matías Romero de Estudios Diplomáticos (SRE) organized a seminar on "Las contribuciones de la inmigración

mexicana a la sociedad de Estados Unidos," which took place on January 24, 1997. Angel Gurría, Secretary of SRE, on the occasion of the Curso de Administración Militar para la Seguridad y Defensa Nacionales, Colegio de la Defensa Nacional, Mexico City, February 7, 1995, referred to the contribution that Mexican workers make to the U.S. economy: He asked that "Estados Unidos reconozca que su mercado continúa demandando la mano de obra mexicana. Debe también reconocer la importante contribución económica que realizan nuestros nacionales...," "Principios, objetivos y estrategias de la política exterior de México en los años noventa," *Discursos del Secretario de Relaciones Exteriores, Angel Gurría,* January- February 1995, p. 15.

15. David M. Kennedy, "Can We Still Afford to be a Nation of Immigrants?" *Atlantic Monthly*, vol. 278, no. 5 (November 1996), 51-68.

16. George J. Borjas, "The New Economics of Immigration, *Atlantic Monthly*, vol. 278, no. 5 (November 1996), 72-80.

17. U.S. Department of Labor, Bureau of International Labor Affairs, *Characteristics and Labor Market Behavior of the Legalized Population Five Years Following Legalization*, May 1996.

18. According to calculations made by the Massachusetts Institute for Social Development, drawing on U.S. Census Bureau data, merchandise exports to Mexico originating in Texas were about $22 billion in 1995 and those from California around $7 billion. According to the Texas Comptroller of Public Accounts, as published in "Fiscal Notes" for October 1995, about 80 percent of the value of U.S. exports to Mexico and about 70 percent of imports pass through Texas land ports. Trucks are the dominant mode of transport, carrying 90 percent of the value of U.S. exports to Mexico and 83 percent of the value of imports.

19. The Gallup 1993 proportion favoring a decrease in immigration (65 percent) conforms with the percentage in a *New York Times*-CBS poll in June 1993. See study by Thomas J. Espenshade and Katherine Hempstead, "Contemporary American Attitudes Toward U.S. Immigration," *International Migration Review*, vol. 30 (Summer 1996), p. 546. The 1995 Gallup Poll figure comes from Espenshade and Maryann Belanger, "U.S. Public Perceptions and Reactions to Mexican Migration," in Frank Bean and others, *At the Crossroads: Mexico and U.S. Immigration Policy* (Lanham, MD: Rowman & Littlefield, 1997).

20. The poll results were released by *La Opinion* on May 21, 1996. The sample was 500 of which 14 percent said in strict confidentiality that they were undocumented aliens, 29 percent U.S. citizens, and 55 percent legal residents.

21. Opinion poll reported by *Este País*, no. 70, January 1997, p. 33. The full executive report of the survey notes that 75 percent of respondents believe that U.S. electoral politics had some influence on the way *indocumentados* are received and treated by Americans. The poll also finds that 80 percent of the respondents consider that the United States has the right to stop the entry of indocumentados. Alduncin y Asociados, "Migración y trato a indocumentados," El Universal/Alduncin y Asociados, 12-16 April, 1996, mimeo.

22. The Mexican survey was carried out in August 1996, by *Reforma* and *El Norte* and consisted of 1500 interviews in the country. The U.S. survey also was carried out in August 1996, by the *Los Angeles Times* and consisted of 1572 interviews with national representation. *Reforma,* September 13, 1996, 6A.

23. Opinion poll by MORI de Mexico, January 1997. Sample size 1150 persons; with national representation.

24. CONAPO, ENCOPLAF 96. The survey size was 3,711 individuals in nine states in Central and Southern Mexico, and was taken in November-December, 1996.

25. Peter Skerry, *Mexican Americans: The Ambivalent Minority* (New York: The Free Press, 1993), 312.

26. Rodolfo O. de la Garza and Louis De Sipio, eds., *Ethnic Ironies: Latino Politics in the 1992 Elections* (Boulder, CO: Westview Press, 1996), 5.

27 Espenshade and Hempstead, "Contemporary American Attitudes Toward U.S. Immigration," pp. 547 and 555.

28. Perhaps the best example was in Orange County, California, where the Mexican-American population showed its power in the defeat of Robert Dornan by a Latina newcomer to politics, Loretta Sanchez. On broader statewide levels, a number of surveys concluded that the Latino vote in California rose from 10 percent of the total in 1992 to between 11 and 13 percent in 1996, from 10 to 16 percent in Florida, and 11 to 12 percent in Texas. See *Washington Post,* November 24, 1996, p. A12.

29. This is the theme of an op-ed column by Paul Gigot, a conservative, Republican-leaning columnist and television commentator, in the *Wall Street Journal*, November 22, 1996, p. A14. One sentence that exemplified the main point of the column is the following: "If Republicans want a reason to worry, they can anticipate the fast-growing Hispanic population voting Democratic the way blacks do now, by more than 80%." William J. Bennett and Jack Kemp made the same point in an earlier op-ed column in the *Wall Street Journal* of October 21, 1994: "The anti-immigration boomerang, if it is hurled, will come back to hurt the GOP."

30. Focus group of entrepreneurs. Alduncin y Asociados, Mexico, D.F., November 12, 1996.

31. This analysis is based on notes and commentary articles published mostly in the second half of 1994 in Mexican newspapers of wide national circulation (See Commissioned Paper: "La Propuesta 187: Debate En Mexico" by Mónica Verea Campos).

32. U.S. press clippings published from October 1995 to April 1996.

33. In their quarrel on this issue, Governor Pete Wilson and Senator Phil Gramm used constitutional arguments. Wilson said his position was justified by the 10th amendment's guarantee of states' rights and Gramm replied that the governor should read further to the 14th amendment which prohibits the denial of equal access to education for any child.

34. Focus Group of NGOs. Alduncin y Asociados, Mexico D.F., November 7, 1996

35. Comisión Nacional de Derechos Humanos, *Segundo informe sobre las violaciones a los derechos humanos de los trabajadores migratorios mexicanos en su tránsito hacia la frontera norte, al cruzarla y al internarse en la franja fronteriza sur norteamericana*, México, 1996. The First Report was published in 1991.

36. Comisión Nacional de Derechos Humanos, *Informe sobre violaciones a los derechos humanos de los inmigrantes. Frontera Sur,* México, 1995.

37. The annual per-country limit for preference visas is 7 percent of the annual total. This annual total of visas available for all preference categories is based on usage during the preceding year, and within a minimum of 366,000. In 1995 the annual total was 400,224, and no more than 28,016 visas could be issued to persons born in any independent country. This number does not include (1) immediate relatives of U.S. citizens (22,016 admitted

from Mexico in FY 95) and (2) 2A preference admissions exempt from the per-country limit (approximately 39,000 from Mexico in FY 95).

38. Section 287 (a)(1) of the INA, 8 U.S.C. sec. 1357 (a)(1) authorizes any officer or employee of the INS without a warrant, "to interrogate any alien or person believed to be an alien as to his right to remain in the United States." Section 287(a)(3) of the Act, 8 U.S.C. sec 1357 (a)(3) authorizes agents, without a warrant "within a reasonable distance from any external boundary of the United States, to board and search for aliens any vessel within the territorial waters of the United States and any railway car, aircraft, conveyance, or vehicle."

39. South Texas Law Journal 26,2 (Summer 1985): 347-356.

40. Unlike criminal proceedings, deportation hearings may proceed in the respondent's absence, and the INS is required only to prove its case using "clear, unequivocal and convincing evidence" rather than satisfying the "beyond a reasonable doubt" standard.

41. 494 U.S. 259, 272 (1990).

42. Id. at 265-266

Sidney Weintraub *1249*

Acknowledgements

The Mexico/United States Binational Study on Migration was a joint effort undertaken by twenty scholars from both countries who worked together in teams on five separate subject areas. The subject areas and team members are listed below. These researchers wrote background research papers and individual team reports, whose information and conclusions were collaboratively condensed and compiled into a joint summary report published under the title *The Binational Study on Migration Between Mexico and the United States*. The present three-volume publication contains the individual team reports (Volume 1) and background research papers and materials (Volumes 2 and 3) that were prepared as part of the Binational Study and that constitute the basis for the joint summary. We are appreciative of the efforts of the team members who, despite their different academic disciplines and subject area expertise, worked in a productive and collegial atmosphere. The summary report, the team reports, and the background papers all demonstrate the commitment of the binational members to producing a state-of-the art assessment of many aspects of Mexico-to-United States migration.

The Binational Study was funded by both the Mexican and United States governments in conjunction with private sector funding in both countries. This

structure was created to optimize the independence of the research teams and to make the final summary report immediately available to institutions interested in the critical role of migration in the bilateral relationship. The Mexican Ministry of Foreign Affairs funded the Study and, with the Ministry of Interior, supported the work of this Study. The U.S. Congress appropriated funds coordinated by the U.S. Commission on Immigration Reform, and both the U.S. Immigration and Naturalization Service and the Department of State made contributions. We also acknowledge funding received from the Consejo Nacional de Ciencia y Tecnología and the United States Information Service in Mexico. Private sector funders were very interested in the project. The Fundación Muguel Alemán in Mexico contributed and the Ford and the Hewlett Foundations in the United States also supported the entire project.

We are grateful for the data and information supplied to the Binational Study by government institutions in Mexico and the United States. We also appreciate the commissioned analyses prepared by Mexican and American consultants to the Study.

Finally, we acknowledge the many individuals in both countries who gave of their time and assisted the Study in gaining invaluable insights above and beyond the more mundane aspects of academic research. The Binational Study alternated its meeting sites between Mexico and the United States and visited several communities in both countries. Government officials were forthcoming in sharing information and hosting opportunities to learn in Mexico City, San Diego, Tijuana, Oaxaca, Washington, San Antonio, and Chicago. The members of the Binational Study especially appreciated the frank exchanges with community residents and migrants in Tijuana, Oaxaca, Guadalajara, and Chicago.

The publication of the present three-volume set did not occur before the U.S. Commission on Immigration Reform sunset on December 31, 1997. Publication was thus subsequently undertaken by the Mexican Migration and Policy Program of The University of Texas at Austin, a joint program of the Lyndon B. Johnson School of Public Affairs and the Population Research Center, under the supervision of Frank D. Bean. The three volumes and the joint summary are also currently available electronically from *http://www.utexas.edu/lbj/uscir*. Special thanks are owed to Anne Isenhower, without whose Herculean and well-organized efforts this project would not have been completed. José A. Arréllaga Acosta, Maria McGivney Arréllaga, Marlena Crusere, Eve Kleinman, Raquel Marquez, Nancy Meredith, Terry Sherrell, and Ruth Whitenton also provided valuable assistance. Other members of the staff of both the LBJ School and the Population Research Center also helped in the publication of these volumes, for which the Binational Study wishes to express its gratitude.

QUANTIFICATION OF MIGRATION

Estimating Unauthorized Mexican Migration to the United States: Issues and Results

Jennifer Van Hook & Frank D. Bean

Issues in Estimating Unauthorized Migration to the United States

Estimates of the size and the growth of the unauthorized migrant population in the United Status have important and far-reaching public policy implications. Such estimates influence assessments of the impact of unauthorized migrants on local labor markets, public welfare resources, school enrollments, and demand for health services. The size of this clandestine population also affects evaluations of U.S. immigration laws, border enforcement policies and the future impact of U.S. immigration and naturalization law. For instance, reliable estimates made during the early 1980s of the unauthorized population helped to predict the likely number of persons seeking legalization under the provisions of the Immigration Reform and Control Act (IRCA) (GAO, 1993; Passel and Woodrow, 1987). Nevertheless, the unauthorized migrant population is difficult to measure directly. Data obtained from survey items about legal status may be highly questionable if not worthless because unauthorized migrants wishing to escape

detection may be unlikely to reveal their status in interviews and/or questionnaires. However, indirect demographic methods for estimating the unauthorized migrant population have been developed and refined over the past twenty years. These efforts have, for the most part, yielded increasingly reliable estimates.

Our purpose is to provide an overview of the best analytical approaches and estimates of the stock and flow of the unauthorized Mexican migrant population from the late 1970s to the present. In doing so, we describe the prevailing methods used for estimating the unauthorized migrant population, including the unauthorized Mexican migrant population, during the late 1970s, 1980s, and 1990s. We thus show how the methodology and data used for making estimates of the stock and flow of the unauthorized migrant population in the United States in general and the unauthorized Mexican migrant population in particular have changed over the past two decades. We highlight how these changes have led to improvements and, in some cases, to increased inaccuracy associated with estimates of particular components of the unauthorized population. We do not review every individual estimate of the unauthorized Mexican migrant population because many studies have already been summarized and evaluated competently in other reviews (Keely, 1977; Briggs, 1984; Siegel, et al., 1980; Hill, 1985; Bean, King, and Passel, 1986; Bean, Telles, and Lowell, 1987; Edmonston, Passel, and Bean, 1990; Passel, Bean, and Edmonston, 1990; Durand and Massey, 1992; GAO, 1993; Clark, et al., 1994). Rather, we summarize and assess the conclusions of these reviews and describe individual studies where appropriate.

This report is divided into five sections. First, we introduce concepts and define the terms that influence both the selection of approaches to estimation and the interpretation of results that have emerged from various estimating procedures. Second, in order to assess their methodologies and results, we review the approaches to estimation of the stock of unauthorized Mexican migrants that have been used since the late 1970s. Third, we conduct a similar assessment for estimates of flows. Fourth, we introduce and discuss several issues whose lack of satisfactory resolution has plagued the conclusiveness and interpretation of the results of almost all estimation approaches. Fifth, given the information and considerations introduced, we briefly summarize the results of the estimates and present, based on the most recent data available, what we think the most satisfactory figures are for the size of the unauthorized Mexican population as of mid-1996.

Concepts and Definitions

An unauthorized migrant is a person who resides in the United States but is not a U.S. citizen or permanent resident alien or authorized visitor. Various terms have been used for identifying unauthorized migrants, including undocumented,

illegal, or unauthorized immigrant, alien, or migrant, each of which has a slightly different meaning and connotation. We use the term "unauthorized migrant" because it is most inclusive of the population we here attempt to describe. Not all unauthorized migrants are undocumented; some arrive in the U.S. with legal documents but later either stay beyond the expiration date of their visa or otherwise fail to comply with the terms of their entry (such as persons who legally cross the border with border crossing cards but do so to work, which violates the terms of the card). Also, not all unauthorized migrants are immigrants; many are temporary migrants who intend to and do in fact return to their countries of origin within reasonably short periods of time.

The types of data available and the methodology used to obtain estimates of the unauthorized migrant population sometimes depend on the route through which unauthorized status was attained. There are several ways to become an unauthorized migrant. These include entering without inspection, using fraudulent documentation, or violating the terms of border crossing cards. All violators of these types end up in a category the Immigration and Naturalization Service (INS) calls entrants without inspection (EWIs). Another way involves entering legally as a nonimmigrant but subsequently violating the terms of the entrance visa or other terms of entry (usually through failing to leave the U.S. by the time the visa expires). These are often called "visa overstayers." Still another way involves entering as a legal resident alien but subsequently violating the terms of entry (e.g., through committing a criminal act or using a fraudulent marriage as a basis for entry). Most studies that attempt to estimate unauthorized migrants separately by type of entry focus on the two largest of these groups, EWIs and visa overstayers.

The data and methodology used to estimate the unauthorized Mexican migrant population also depend on whether the estimate refers to the stock of the population or the flow of the migratory stream. Stock refers to the size of the population at a particular point in time. Flow refers to the number of *entrances* into (in-flow) and *exits* from (out-flow) the population during a given time period. Most estimates of the volume of the migratory flow have focused on in-flow. In-flow in turn may be subdivided into *gross* in-flow and *net* in-flow. Gross in-flow is the total number of entrances made during a given time period whereas net in-flow is the number of persons entering during a given time period. Because an individual may enter the country as an unauthorized migrant more than once in a single time period, net in-flow is almost by definition smaller than gross in-flow. In contrast to in-flow, relatively little attention has been paid to the size and components of the out-flow of unauthorized migrants. Persons may exit unauthorized status through death, emigration, deportation, or legalization. Out-flow is a critical component because the majority of entrances are offset by exits, as indicated by estimates of net flow. Observers who fail to account for out-flow risk highly exaggerated estimates of the

rate of growth of the unauthorized migrant population. More attention has been paid to estimating net flow (in-flow minus out-flow). Net flow has typically been estimated as the change in stock as it is estimated at two or more points in time (Passel and Woodrow, 1987; Woodrow, Passel, and Warren, 1987).

Another conceptualization which is related to the idea of stocks and flows but is analytically distinct is the notion of temporary or permanent migrants, or sojourners and settlers, to use the more sociological distinction (Bean, Vernez, and Keely, 1989; Chavez, 1988). Here the reference is to the duration of stay in the destination country, but especially to the migrant's *intended* duration of stay (Roberts, 1995). Such intentions have consequences because the kinds of immigration and settlement policies that might be invoked in the cases of temporary and permanent migrants are not necessarily the same (e.g., see Passel, 1986). Further complicating the situation is that many temporary migrants undergo a transition to permanent migrants over time. Apart from their sociological and policy significance, temporary and permanent migrants may be thought to differ only in duration of stay. At any point in time, estimates of the "stock" of Mexican migrants will include both permanent and temporary migrants, the latter of whom we would expect disproportionately to return to Mexico within short periods of time. From a strictly temporal point of view, of course, the only distinction between these kinds of migrants is their length of stay in the United States. One of the challenges facing the estimation of stocks and flows of migrants, as we note below, is to develop more complete information on the duration of stay distribution of migrants, especially by sex, age at migration, and mode of entry. If such information were available, it would be relatively straightforward to develop estimates of stocks and flows of migrants. Of course, the sociological differences (and their attendant policy implications) between migrants who intend short or long durations of stay would nonetheless remain significant.

Based on the distinctions of mode-of-entry (EWI vs. overstayer) and of intended duration of stay, we may construct a four-fold classification of unauthorized entrants (see Figure 1). The groups represented by the boxes (bottom row) in this classification are important because they have implications for policy. Much of the historical and current debate in the United States about unauthorized migration derives from differences in perceptions about which of these categories dominates the flow of migrants, thus affecting growth in the stock of unauthorized migrants. During the 1970s, for example, many observers confused the concepts of stock and flow, mistaking evidence about large numbers of entrances for a sizable stock of migrants. In effect, their error was to assume that permanent EWIs substantially predominated over temporary EWIs, when at that point in time just the opposite was true. Now immigration analysts debate the relative importance of the EWI versus the overstayer flow, a debate that is not likely to

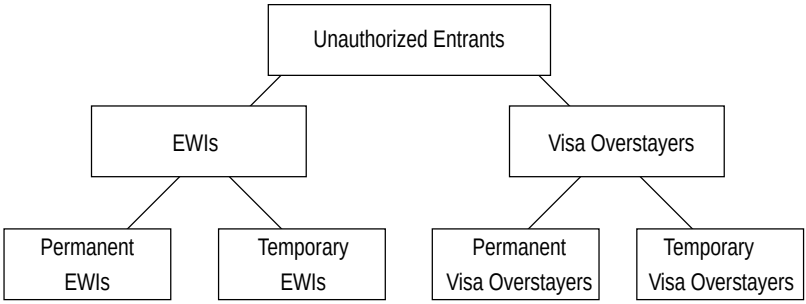

Figure 1. Analytic Typology of Kinds of Unauthorized Entrants Based on Mode of Entry and Intended Duration of Stay

be resolved until we can ascertain the relative size of the temporary versus permanent (or short-term versus long-term) component of *each* flow. Thus, if virtually all visa overstayers were found to return to their countries of origin within a couple of years of violating the terms of their visa, estimates of the stock of overstayers would consist primarily of temporary migrants, however numerous such persons might be at a given moment in time. This scenario would have different policy implications than one in which visa overstayers were generating large numbers of permanent migrants.

Approaches to the Estimation of the Stock

Speculative Estimates

Early efforts to determine the size of the total unauthorized migrant population produced results that were highly speculative, ranged widely, and were usually much higher than analytic estimates (Keely, 1977; Siegel, et al., 1980). Based on a series of "educated guesses" in relation to the number of INS apprehensions of unauthorized migrants, INS Commissioner Farrell (1972) testified that the total unauthorized population exceeded one million in 1972. Three years later, INS Commissioner Chapman (1975) raised Farrell's estimate to 4 to 12 million largely in an effort to create a public issue about unauthorized migrants and to increase federal funding for the INS (Keely, 1977). Subsequent speculative estimates put the unauthorized population at 8.2 million (Lesko Associates, 1975), 6 million (Chapman, 1976), and 3 to 6 million (Castillo, 1978). Despite improvements in methodology, which produced lower and increasingly reliable appraisals of the size of the unauthorized population, speculative estimates continued to drive the debate about unauthorized immigration as it was played out in the media as well as in Congressional hearings during the 1980s (Bean, Telles, and Lowell, 1987). As

recently as the mid-1980s, Corwin (1982) asserted, based primarily on conjecture, that the Mexican unauthorized migrant population was as large as 8 to 10 million, and Huddle, et al. (1985) selected the middle of Corwin's range as their best estimate.

Early Analytic Estimates

Despite methodological difficulties and persistently large ranges, early analytic studies produced estimates of stock that failed to support the speculative assertions that there were more than 6 million unauthorized migrants in the country. One salient characteristic about the analytic studies of the size of the unauthorized population conducted during the 1970s is that they developed a wide variety of estimation techniques and often made creative use of available data. We list these studies in Table 1. Early analytic estimates of the total unauthorized migrant population were based on a variety of U.S. data sources. For example, Korns (1977) compared CPS employment data with the Labor Department's payroll survey measure of employment. By assuming that unauthorized migrants are not included in the CPS data but are present in the payroll data, he concluded that the number of unauthorized workers grew by 2 million between 1965 and 1969, but did not increase substantially during the 1970s.

Using a more statistically sophisticated approach, Lancaster and Scheuren (1977) matched CPS, IRS, and Social Security records of persons age 18-44 in 1973, and, using a log-linear technique, estimated the number of persons not represented in any of the three data sources. Finally, they compared the sum of the those estimated to be both in and out of the three data sources with the total estimated from the 1970 Census. On the assumption that no unauthorized migrants were enumerated in the 1970 Census—an assumption that has been supported by Census Bureau researchers (Fay, Passel, and Robinson, 1988)—they interpreted the differential as the number of resident unauthorized migrants age 18 to 44. Due to uncertainties associated with the data and the log-linear estimation technique, their estimate ranged from 2.9 to 5.7 million. Robinson (1980) used U.S. death statistics to estimate the male unauthorized population age 20-44 in 1975. Robinson assumed that most deaths to unauthorized migrants are registered in U.S. vital statistics, but that few or no unauthorized migrants are included in the 1970 census. Then, in areas where large unauthorized migrant populations were assumed to concentrate, death rates that were higher than other parts of the country were interpreted as due to "excess deaths" to unauthorized migrants. Robinson's "composite" estimates ranged between 2.6 and 3.2 million, but his more conservative estimates, which allowed for a broader range of underlying assumptions, ranged widely from 0.6 to 4.7 million. The validity of estimates produced by this method was severely weakened because death rates and patterns in cause of death among the

Table 1
Studies with Implications for Underenumeration

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
Goldberg (1974)	1960-1970	Net unauthorized immigration from Mexico	Projection of 1960 Mexican Census population to 1970	1.6 million
Korns, Alexander (1977)	1960-1970 (?)	Non-ag. unauthorized workers	Comparison of CPS employment and Department of Labor payroll data	Increase between 1965 & 1969 = 2,000,000; no substantial increase in the 1970s
Lancaster and Scheuren (1977)	April, 1973	unauthorized migrants	Comparison of matched CPS, IRS, and Social Security files with 1970 Census population	2.9 to 5.7 million age 18-44 for all ages added 10%
CENIET—Garcia y Griego (1979)	1977	unauthorized Mexican migrant workers	Border interviews w/ unauthorized migrants INS apprehended and returned to Mexico	0.5 to 1.2 million
CENIET—Zazueta and Corona (1979)	1979, and 1974-1979	Legal and unauthorized Mexican migrants workers	Data: National Survey of Emigration. Asked if household member age 15+ currently in the U.S.	519,300 Mex. workers, Jan. 1979; 91% undoc.; 85% male; implies 472,700 undocs.
CENIET—Garcia y Griego (1980)	1978	unauthorized Mexican migrant workers	Data: INS apprehensions; migration histories of 822 Mexican males, 1973, prior to entry	1978: 482,000 - 1,224,000; 1972: 234,000 - 436,000.
Robinson (1980)	1960-1970 and 1970-1975	Male unauthorized migrants age 20-44 in NY, NJ, IL, MI, FL, TX, CO, NM, AZ, and CA	Trends in age-specific death rates. 1975: 577,000 - 4,673,000	1970: 177,000 - 1,930,000 assumptions.
CIENIET: Zazueta (1982)	April, 1978	unauthorized Mexican migrant workers	see Zazueta and Corona, 1979	405,467 Mexican workers age 15+ (346,406 males, 81% age 15-39)
Diez Canedo (1984)	1975	Mexicans in the United States	Total remittances from U.S. to Mexico divided by the average remittance	481,000

unauthorized population were and remain unknown. Also, Robinson's estimates lacked precision because death records contained no information on place of birth until 1983 (GAO, 1993).

Early estimates of the Mexican unauthorized population relied on Mexican census or survey data. Goldberg (1974), using 1960 and 1970 Mexican census data, projected forward the Mexican 1960 population to 1970 by adding births and subtracting deaths and known legal emigration from Mexico to the United States. The difference between the 1970 census population and the projected population—about 1.6 million—was taken as an estimate of the size of the U.S. resident Mexican unauthorized population in 1970. One problem with Goldberg's estimate is that its underlying assumption—that the coverage of the Mexican Census remained the same from 1960 to 1970—cannot be substantiated. This is important because small differences in coverage can lead to large differences in the final estimate (Siegel, et al., 1980).

Another set of estimates were based on Mexican survey data collected by the Mexican Government (CENIET). These surveys were more successful at describing the sojourner than the settler population among Mexican emigrants to the United States. Garcia y Griego (1979; 1980) used migration histories collected from a small sample of Mexican male migrants to estimate that 0.5 to 1.2 million unauthorized Mexican workers resided in the United States in 1977 and 1978. Zazueta and Corona (1979) and Zazueta (1982) relied on data obtained from Mexico's National Survey of Emigration, which asked households about members age 15 and older who were either working or looking for work in the United Status. They estimated that 400,000-500,000 Mexican workers lived in the U.S. around 1978 and 1979, 90 percent of whom were unauthorized. This estimate has been criticized as being too low, not because it is implausible for the population it describes (Durand and Massey, 1992), but because it does not include children, adult dependents, or those who do not have household members living in Mexico (Siegel, et al., 1980). Finally, Diez Canedo (1984) estimated that 481,000 Mexican workers were living in the United States in 1975. This estimate was made by calculating the total remittances sent from the U.S. to Mexico and dividing by the estimated average remittance made by migrant workers to their households in Mexico. This estimate is similar to that produced by Zazueta and Corona (1979) and Zazueta (1982), most likely because it describes a similar population, namely Mexican workers in the United States who maintain linkages to households in Mexico.

Stock Estimates Based on Residual Methods

Estimates of the size and growth of the unauthorized migrant population in the late 1980s and 1990s attempted to address some of the shortcomings of previous

work. During the 1980s, the majority of these new studies employed a residual method of one form or another. Residual methods provide an estimate and description of the "enumerated" unauthorized migrant population, that is, the part of the unauthorized population that is enumerated in the Census or represented in a sample such as the Current Population Survey (CPS) (the unenumerated portion of the population must be estimated by other means, as we discuss below). The enumerated unauthorized population is estimated as the difference between the non-citizen population enumerated in the Census or the CPS and the legally resident alien population (enumerated non-citizens—legally resident aliens = enumerated unauthorized resident migrants). This computation may be done separately by national origin, period of entry, age, sex, and, depending on the level of detail available in estimates of the legal population, by state and metropolitan area. Hence, a substantial amount of information about the enumerated unauthorized migrant population may be produced by residual methods. Studies that use a residual method are listed in Table 2. Most of these studies were conducted by the Bureau of the Census. Except in the case of Heer (1979) and Warren (1982), residual methods were generally not employed with data collected prior to the 1980s because the 1980 Census was the first decennial census in which a sizable *enumerated* unauthorized migrant population could be detected through demographic analysis (Fay, Passel, and Robinson, 1988).

Residual estimates of the enumerated unauthorized population are highly sensitive to estimates of their two components, the enumerated non-citizen and the legally resident alien populations. In the series of residual estimates made by Census Bureau researchers, the enumerated non-citizen component was routinely adjusted for errors associated with respondents not reporting country of birth, misreporting citizenship status, and misreporting nativity. The task of approximating the number of legally resident non-citizens presented greater difficulties. Because respondents are not asked about legal status in the Census or the CPS, estimates of the legally resident alien population must be obtained from external sources. Due to changes in the external data sources available and changes in the legal population brought about by the IRCA amnesty program, three different methods have been developed to estimate the size and composition of the legal immigrant population. We discuss each of these below.

The first relies on data obtained from the Alien Registration Program (form I-53) by the INS. We refer to residual methods that uses the I-53 data as *Residual Method 1*. Until 1981, the INS annually collected data on residence and other items from legally resident non-citizens. Because of the discontinuation of the Alien Registration Program after 1981, the only studies that have used Residual Method 1 include an analysis of the 1980 Census (Passel and Woodrow, 1984; Warren and Passel, 1984, 1987; Passel, 1985b) or CPS data pertaining to a year prior to 1980

Table 2

Residual and Other Estimates of the Stock of the Unauthorized Migrant Population in the United States

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
Heer (1979)	1970 - 1975	Net flow of unauthorized migrants (EWIs) from Mexico	Residual Method 1	82,300 - 232,000 per year; Author's favorite: 116,000 per yr.
Warren (1982)	1979	Unauthorized migrants in 1979 November CPS	Residual Method 1	Total: 1,250,000 Mexican: 734,000
Passel and Woodrow (1984)	1980	Unenumerated unauthorized migrants in the 1980 Census, by state	Residual Method 1	Total: 2,060,000 (CA = 49.8%) Mexican: 1,131,000 (CA = 67.5%)
Warren and Passel (1984)	1980	Unauthorized migrants in 1980 Census	Residual Method 1	931,000 Mexicans
Passel (1985b)	1980	Estimates for SMSAs of unauthorized residents in 1980 Census	Residual Method 1	Sum is consistent with national estimates
Passel and Woodrow (1987)	Nov., 1979 April, 1983	Unauthorized Migrants, total and Mexican, age 14+	Residual Methods 1and 2	1979: 1,273,000 (Mex.: 917,000) 1983: 2,093,000 (Mex.: 1,422,000)
Warren and Passel (1987)	1980	Unauthorized migrants in 1980 Census	Residual Method 1	Total: 2,057,000 Mexican: 1,131,000
Woodrow, Passel and Warren (1987)	June, 1986	Unauthorized migrants in CPS	Residual Method 2	Total: 3,158,000 Mexico: 2,200,000
Woodrow and Passel (1990)	June, 1988	Unauthorized migrants in CPS	Residual Method 3	Total: 1,906,000

Table 2 (Continued)

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
Woodrow (1991a)	Nov., 1989 April, 1990	Total and enumerated unauthorized migrant populations	Residual Method 3, and various assumptions about undercount	Total: 3.3 million (1.7 to 5.5 million) 1989 CPS: 2.05 million (1.1 to 2.0 million if SAWs included), 1990 Census: 2.4 million (1.8 to 3.2 million)
Woodrow (1992)	1990	Published version of Woodrow (1991a)		
Clark, et. al. (1994)	1990	Unauthorized migrants in the 1990 Census	Residual Method 3 with different assumptions (include half of SAWs in legal population)	1,975,000
Bean, King, and Passel (1983)	1980	Mexican unauthorized migrants	Sex-ratio, age distribution assumptions Data: Mexican Census	1.5 - 3.8 million (no more than 4 million)
Warren (1995)	1990 and Oct., 1992	Total and Mexican-born unauthorized migrants	Constructive Method based on CPS residual estimates, Visa overstayers, and IRCA non-applicants	1990: Total: 2,600,000 Mexican: 1,009,000 Oct., 1992: Total: 3,400,000 Mexican: 1,321,000
INS (1997)	Oct. 1996	Total and Mexican-born unauthorized migrants	Constructive Method based on CPS residual estimates, Visa overstayers, and IRCA non-applicants	Total: 5 million Mexican: 2.7 million

(Heer, 1979; Warren, 1982). These studies found that about 2.057 million unauthorized migrants and 1.131 million unauthorized Mexican migrants were enumerated in the 1980 Census. The unauthorized population in the Census included more women and children than indicated in apprehensions and Mexican migrant history data. Because residual methods probably identify settlers better than sojourners and commuters, this suggests that the settled part of the unauthorized population includes a greater proportion of families and children than does the commuter and sojourner portions of the unauthorized population (Warren and Passel, 1987, see also Muller and Espenshade, 1985).

One problem associated with Residual Method 1 is that about 11 percent of legal immigrants were found to be missing from the I-53 data. Therefore, estimates of the legal alien population had to be carefully adjusted for undercoverage (Warren and Passel, 1984; 1987). Another difficulty associated with Residual Method 1 is that it makes the assumption that all legal non-citizens are enumerated in the census or CPS (Woodrow-Lafield, 1995; Woodrow, Passel, and Warren, 1987). If legal non-citizen migrants had a undercount rate as high as five percent, for instance, then the number of legal non-citizens enumerated in the 1980 Census would be overstated by about 300,000, and the number of unauthorized migrants would be underestimated by the same amount. Warren and Passel's (1987) estimate of 2.057 million enumerated unauthorized migrants would then have to adjusted upward to about 2.357 million.

The limitations associated with Residual Method 1 are small in comparison to its advantages. The availability of Alien Registration data permitted researchers to estimate directly the legally resident population rather than having to construct it from INS immigration records and estimates of mortality and emigration. Also, Alien Registration data allowed researchers to determine at the state and metropolitan levels the size of local legal migrant populations. This level of geographic detail thus permitted the generation of estimates of the unauthorized population by state (Passel and Woodrow, 1984) and metropolitan area (Bean, Lowell and Taylor, 1988; Passel, 1985b). Such studies showed that unauthorized migrants concentrate in areas that have large legal immigrant populations, namely metropolitan areas in California, New York, Texas, Illinois, and Florida. The results also indicated that among all states in 1980, California contained the largest share of unauthorized immigrants, accommodating 49.8 percent of all unauthorized migrants and 67.5 percent of unauthorized migrants originating in Mexico.

After 1981, the Alien Registration Program was discontinued. As a result, estimates of the legal alien population had to be constructed by projecting forward the 1980 adjusted Alien Registration population to the appropriate year. For each year of projection, numbers of new legal immigrants, refugees and other long-term legal nonimmigrants were added and numbers of emigrants and deaths due to the

legally resident foreign born were subtracted. Residual methods that use this procedure are here referred to as *Residual Method 2*. The Census Bureau used Residual Method 2 to estimate the unauthorized population enumerated in the CPS during the 1980s up until the enactment of the IRCA legalization programs in 1988. These studies include analyses of the April 1983 (Passel and Woodrow, 1987) and the June 1986 CPSs (Woodrow, Passel, and Warren, 1987), which were the only CPS data collected before 1988 that included information about nativity. These studies concluded that by June 1986, about 3.158 unauthorized migrants, 2.196 million of whom were born in Mexico, were detected by the CPS. More importantly, by this time the Census Bureau had compiled consistent estimates of the unauthorized population enumerated in the CPS from 1979 to 1986. Assuming that the rate of undercoverage was consistent across the CPS samples, reliable estimates of net growth of the unauthorized population could be made. The studies indicate that the unauthorized migrant population grew during the early 1980s by about 218,000 per year, and the Mexican-origin unauthorized population by about 115,000 per year. Due to uncertainties associated with assumptions about emigration and disproportionate undercoverage, however, the authors conceded that the annual net growth of the unauthorized population could have been in the range of 100,000 to 300,000, with about half of the growth due to growth in the Mexican-origin unauthorized population.

Most of the error associated with estimates that use Residual Method 2 is due to uncertainties associated with emigration rather than immigration or mortality. The INS keeps accurate records of the number and types of legal immigrants. Also, the component due to mortality is small in comparison to the other two components of change, so the proportion of total error due to error in the number of deaths is small (Himes and Clogg, 1992). However, the INS has not collected data about emigrants since 1957. During the 1980s, the Census Bureau routinely used a mid-range estimate of 133,000 foreign-born emigrants per year. This approximation was based on the results of research pertaining to the 1960s (Warren and Peck, 1980) and the 1970s (Warren and Passel, 1987). During the 1980s, attempts were made to update estimates of the emigration component by analyzing special items included in the CPS during the late 1980s that asked respondents about relatives who emigrated (Woodrow-Lafield, 1996). Although the results of this work do not contradict the estimate of 133,000, it also indicates that other estimates of the annual number of emigrants ranging from about 110,000 to 200,000 would be plausible. To the extent that the actual annual number of emigrants during the 1980s were consistently higher than 133,000, the legal migrant population would have been overstated and the enumerated unauthorized migrant population would have been set too low. The opposite would be the case if the actual annual number of emigrants had consistently been lower than 133,000. Because annual

estimates of emigration are subtracted from the legal alien population for each year the population is carried forward, the error associated with emigration increases with each additional year. In other words, the longer the time data sources on the legal migrant population or emigration are not available, the greater the uncertainty associated with residual estimates.

Another source of error in estimates produced by Residual Method 2 relates to assumptions about undercoverage of the legal immigrant population. As does Residual Method 1, Method 2 assumes that all the legal non-citizens are enumerated. In addition, Residual Method 2 assumes that all immigrants who arrived since 1980—regardless of citizenship status—are represented in the CPS. The bias associated with this additional assumption most likely increases over time as the proportion of the immigrant population who arrived after 1980 grows. The error due to this bias is increased even more for the above cited studies because they analyzed CPS rather than census data and the CPS has higher levels of undercoverage than the census (Woodrow, 1991). That is, residual estimates of the enumerated unauthorized population are understated the most when undercount rates of the legal population are the highest. Of course, if the error associated with emigration leads to an overestimate of the unauthorized population, then part or all of the underestimation due to assumptions about undercount of the legal population may be canceled out.

Starting in 1987, about 1.7 million long-term unauthorized migrants and an additional 1.3 million unauthorized special agricultural workers (SAWs) applied for legalization under the amnesty provisions of the 1986 Immigration Reform and Control Act (IRCA). As a result, post-1987 residual estimates of the unauthorized migrant population have to be adjusted to account for this increase in the legal population. In this variation of the residual method, which we refer to as *Residual Method 3*, the legal population is constructed in the same way as in Residual Method 2, only the number of IRCA legalized migrants are added to the estimate of the legally resident foreign-born population. Studies that used this method include analyses of the June 1988 (Woodrow and Passel, 1990) and the November 1989 CPS files (Woodrow, 1990, 1991, 1992), and the 1990 Census (Woodrow, 1991; GAO, 1993; Clark, et al., 1994). The results of these studies show that about 2.3 million (ranging between 1.8 to 3.2 million) unauthorized migrants were enumerated in the 1990 Census, about 80 percent of whom were born in Mexico. This research also indicates that had IRCA not taken effect, the unauthorized population would have grown by roughly 200,000 annually between 1986 and 1990, reaching a size 70 percent larger in 1990 than was observed. Most of this difference was due to the large numbers of Mexicans who legalized under IRCA; Mexicans comprised more than 70 percent of the IRCA legalized population (Woodrow and Passel, 1990).

The limitations associated with Residual Method 3 are the same as those associated with Residual Method 2. In addition, estimates produced by Method 3 may be inaccurate because it is unclear what fraction of the SAW legalized population remained resident in the United States after legalization. Many SAW applicants presumably were seasonal migrant workers who spent a portion of each year in Mexico. Whether to include the SAW population in estimates of the legally resident population is important because each addition to the legal population results in a one-to-one decrease in the estimated unauthorized population. Even though researchers tend to focus on the number of SAWs who were resident in the United States at the time of the Census, it is more important to focus on the number of SAWs who were actually enumerated in the Census. The Census Bureau assumes that an insignificant number of SAWs were enumerated in the Census or CPS. Hence, they do not include the 1.3 million SAWs in estimates of the enumerated legally resident alien population (although they do provide ranges of estimates that result from varying assumptions about coverage of the SAW population).

Clark, et al. (1994) attempt to make estimates based on more plausible assumptions. They assume that in the SAW legalized population, all pre-1984 entrants, all non-Mexicans, and about half of the remaining post-1984 entrants were resident in the United States at the time of the 1990 Census. This amounts to 728,000 or about half of the SAW population. Clark, et al. (1994) include all 728,000 in estimates of the legally resident population, resulting in an estimate of only 1.975 million enumerated unauthorized migrants in 1990 (in comparison, the Census Bureau made a "preferred" estimate of 2.390 million)[1]. Although it does seem implausible that no SAWs were resident nor enumerated in 1990, the Clark, et al., estimate of 728,000 could be too high. Even if half of the SAW population were *resident* in the United States in 1990, it is doubtful that more than 40 to 50 percent of this group were *enumerated*. Migrant agricultural workers have the highest rates of undercount among all groups, reaching 60 to 70 percent (Gabbard, Kissam, and Martin, 1993). However, there is evidence that a large number of SAW applicants were not really farm workers, plus there is no guarantee that farm workers in 1988 continued to be farm workers in 1990. Hence, more SAWs may have been resident in the United States in 1990 than many analysts have thought, and since many of the SAWs may have been working outside agriculture, they may have had higher coverage rates than has previously been assumed. We introduce below new evidence about the residency patterns of the SAW population in the early 1990s.

In sum, residual methods provide reliable, consistent estimates of the size and growth as well as detailed descriptions of the resident unauthorized migrant population. In comparison with earlier analytic studies, the studies that used residual methods during the 1980s and early 1990s were more successful at describing, quantifying, and reducing the range of error associated with their estimates.

Unfortunately, the range of error is likely to grow over time as information about emigration and the size and geographical residence of the legal immigrant population become increasingly out-of-date, and as other changes occur in the legal population, such as those brought about by IRCA. Unless other methods for obtaining accurate information about emigration or the legal immigrant population are developed, residual methods will probably dominate the literature to a lesser extent in the future than they did during 1980s. Another important limitation of residual estimates is that they describe a selective part of the unauthorized population, namely the portion that is probably least mobile and most permanently established. As we describe in a separate technical appendix, other methods must be used to estimate the total and unenumerated portions of the stock of the unauthorized migrant population.

Other Approaches to Estimating Stocks

Other approaches to estimating the stock of unauthorized migrants used during the 1980s and 1990s include a sex-ratio based method and a constructed components method. Bean, King, and Passel (1983) developed a range of estimates by examining sex ratios from the 1980 Mexican census. Given that Mexican emigration is age- and sex-selective, and that it occurs almost exclusively to the United States, this research was able to estimate the number of persons "missing" from the age and sex structure of the 1980 Mexican population expected in the absence of emigration. Assumptions were made about differential census coverage by gender, the proportion male among all emigrants aged 15-39, and the proportion of all emigrants aged 15-39. After estimating numbers of Mexican emigrants for various combinations of assumptions, estimates of unauthorized migrants were developed by subtracting the number of I-53 reporting Mexican legal immigrants in the United States, adjusted for underreporting. A major criticism is that the results obtained are highly sensitive to the assumptions used, but a benefit is that the approach does provide estimates of the total size of the unauthorized Mexican population, not just the enumerated part of the population. The figures obtained ranged from 1.5 to 3.8 million, establishing an upper-bound estimate for 1980.

The most widely known and cited set of recent estimates of the stock of unauthorized migrants has been constructed by the U.S. Immigration and Naturalization Service (1997). Estimates are developed for each of the states in the United States and for each of 99 countries of origin. The approach seeks to take advantage of information obtained after IRCA about the numbers and characteristics of unauthorized migrants legalizing their residence in the United States under the provisions of IRCA. The INS estimate is not predominantly a residual estimate, but rather involves starting with a 1982 estimate and then adding and subtracting

components of change to bring the figure forward to October 1996. The approach combines information about IRCA's legalization applicants with results obtained from using both the residual method to estimate net EWIs and the overstay method (see below) to estimate overstayers. Applying these procedures to construct the components of the unauthorized population results in an estimate of five million unauthorized migrants resident in the United States by October 1996, of whom 2.7 million were estimated to be from Mexico and another 660,000 from El Salvador, Guatemala, Honduras, and Nicaragua. Fifty-nine percent of the total was estimated to have "entered without inspection" and 41 percent to be "visa overstays." Most of the Mexicans were estimated to have entered the country as EWIs.

Approaches to the Estimation of Flows

Speculative and Early Estimates

In comparison of estimates to stock, few speculative estimates have been made about the rate of growth of the unauthorized population. Chapman (1976) guessed that the population grew by 500,000 per year, and Reubens (1980) estimated an annual growth of 600,000 during the 1970s. Despite analytical evidence that the annual growth of the unauthorized population was considerably less than the speculative estimate of 500,000, the media and others continued to cite the number. As Passel (1985: 6) chided, "The figure of 500,000 per year is widely used even though there is no strong empirical support for selecting this figure over any other. It seems to be popular because it is a nice 'round' figure that is easy for the public to accept."

Analytic estimates of the volume of in-flow and net flow of the unauthorized population tended to refer to different parts of the unauthorized population and ranged widely. These studies are listed in Table 3. Garcia y Griego (1980), using Mexican survey data on migration histories, estimated that the annual in-flow from Mexico of unauthorized migrants in 1975 ranged from 75,000 to 284,000. Others used INS apprehensions data as a proxy for general patterns in the level of flow of EWIs from Mexico (e.g., North, 1975; Frisbie, 1975). The difficulties associated with using apprehensions data as a proxy for the flow of EWIs are (1) that apprehensions data do not include those who succeed in evading detection, and (2) that apprehensions data count arrests, not individuals; arrest data are potentially misleading because they include multiple arrests by the same person. The INS (1976) attempted to estimate the component of fraudulent successful entries by conducting field studies at 15 Mexican border entry points and 10 major international airports. Two teams of immigration inspectors were stationed at each entry point and carried out careful inspections of entrants for fraudulent documents and intent

Table 3

Analytic Estimates of the Flows of the Unauthorized Migrant Population to the United States

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
North (1975)	1960s-1970s	Flow of unauthorized migrants	Apprehensions	Rise in flow during the 1960s, but not in the 1970s.
Chapman (1976)	1974-1976	Non-immigrant Visa-overstays	Matched Visa entrance and departure records of non-immigrants	740,000 failed to leave on time since 1974; over 1,000,000 from before 1974.
U.S. Department of Justice, INS (1976)	1975	Unauthorized migrants entering with fraudulent documents or intents to violate Visa terms	Thorough INS inspections at border points and at 10 major airports, Sept. 1975-Feb. 1976	500,000 successful fraudulent entries
Heer (1979)	1970-1975	Net flow of unauthorized migrants (EWIs) from Mexico	Residual Method 1, CPS data	82,300-232,000 per year; Author's favorite: 116,000 per yr.
CENIET-Garcia y Griego (1980)	1978	Unauthorized Mexican migrant workers	INS apprehensions; migration histories of 822 Mexican males, 1973, prior to entry	Net inflow 1975-1976: 75,000-284,000 problems
Passel and Woodrow (1987)	April, 1980-April, 1983	Annual net flow of unauthorized migrants, age 14+	Residual Methods 1 and 2	100,000 to 300,000 per year
Woodrow, Passel and Warren (1987)	1979-1986 and 1980-1986	Net flow of unauthorized migrants	Residual Methods 1 and 2	1980-86: Total 176,000 per year Mexican 170,000 per year 1979-86: Total 218,000 per year Mexican 115,000 per year

Table 12 (Continued)

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
Bean, Espenshade, White, and Dymowski (1990)	Nov., 1986-Sept., 1989	Net flow of EWIs (Southern border)	Data: INS apprehensions, controlled for population in Mexico at risk of migration (age 15-34), number of SAWs, and wage and employment ratios	Apprehensions have seasonal pattern, have dropped post-IRCA, and have increased among women and children
Espenshade (1990)	Nov., 1986-Sept., 1988	Gross flow of unauthorized Mexican EWIs (Southern border)	Repeated trials model	Per month: 175,000 unauthorized entries Total: 4,000,000 from 1986-1988
Warren (1990)	1985-1988	Non-immigrant Visa-overstays by country of origin	INS matched arrival and departure records	Annual number: 217,000 to 255,000 (fluctuated by year). Primary country of origin is Mexico
Espenshade (1995a)	1977-1988	Gross flow of EWIs (Southern border)	Repeated trials model	Correlation between apprehensions and flow = 0.9; Flow = 2.2 * apps.

to violate visa terms. Based on this work the INS concluded that there were 500,000 fraudulent entries into the United States in 1975, although these estimates have been severely criticized because of small sample sizes and variable rates of detection depending on the day of the week, the immigration inspector, and point of entry (Keely, 1977).

Chapman (1976) attempted to measure the visa overstay component of the in-flow of unauthorized migrants by matching INS records of nonimmigrant visa entries and departures. He estimated that from 1974 to 1976, 740,000 nonimmigrants (about 250,000 annually) failed to leave the United States on time. These estimates were almost certainly too high because they included nonimmigrants who left the country but whose departure forms were never filed, were lost, or otherwise never successfully matched with an arrival form. The size of this error was probably large. At the time, the INS collected about six million entrance forms from nonimmigrants per year, and departure forms were linked with arrival forms by matching the name of the nonimmigrant (Siegel, et al., 1980).

Summed together, the estimates of in-flow of EWIs and visa overstayers easily matched and even exceeded the speculative estimate that the unauthorized population grew at a rate of 500,000 per year. However, analytic estimates of net flow showed that the out-flow component of the unauthorized migrant migration stream offset much of the in-flow component. Based on an analysis of CPS data, Heer (1979) estimated that the unauthorized Mexican population grew by about 116,000 annually from 1970 to 1975. Although Siegel, et al. (1980) criticized the estimate because of its large sampling error, they concluded on the basis of the study and other evidence that much of the unauthorized migration to the United States appeared to be circular and was offset by return migration to Mexico.

Studies of flow conducted during the 1990s have exploited the availability of new data and new estimation techniques. The INS has long matched arrivals with departures (NIIS), terming arrivals that do not match with departures apparent overstays. The latest research using this data goes one step further by attempting to eliminate system error in the data (Warren, 1990). System error refers to false overstays. INS data for 12 countries which are assumed to have no overstays are used to determine the extent of system error (Belgium, Netherlands Antilles, Norway, Sweden, Kuwait, Saudi Arabia, Switzerland, Australia, New Zealand, Surinam, Singapore and Finland). System error is computed separately by class of admission. First, overstays are estimated for each country using the Nonimmigrant Information System (NIIS). Next, system error is subtracted from the rate of apparent overstay. The remainder is multiplied by the number of expected departures to equal the estimated number of overstays. For estimation by state of destination and age, a calculation was made for each category by state or age. The rate of system error was adjusted to match those of the countries.

Nonimmigrant arrivals increased from 9.4 million in 1985 to about 14.3 million in 1988. The annual number of overstays has fluctuated around 217,000-255,000 (increasing by 12% in 1986 and dropping 7% in 1987 (following IRCA) and increasing 13% in 1988). The level of system error has dropped continually (10.3% in 1985 to 8.1% in 1988). North America has been the primary region of origin for overstayers (with the most growth occurring among those from Mexico). The top five countries of origin (Mexico, Haiti, the Philippines, Poland and India) were also among the leading countries for application for legal residence under IRCA. Looking at the geographic distribution of those overstaying their visa time limits, those states with the largest foreign-born population also attracted the most overstays. Finally, Warren finds that most overstays were between ages 15 and 44.

Two primary assumptions are associated with this estimation procedure: (1) that there are few actual overstays from the 12 benchmark countries selected so all apparent overstays from these countries are assumed to represent system error and (2) that a single point estimate of system error applies to every country within a category of admission. In addition, the estimates exclude immigrant students who overstay and all those who enter the United States without inspection (EWIs). In a modification of the procedure undertaken as a result of a GAO (1995) scrutiny of the approach, system error was re-estimated on a airline-by-airline instead of country basis. While the revision resulted in somewhat higher or lower figures for a few countries, the overall result was nearly identical to the figures obtained using the previous method.

Another way to estimate the flow of unauthorized immigrants to the United States is to use apprehensions data from the U.S. southern border. Apprehensions data have been used as a proxy for unauthorized migration flows (Frisbie, 1975; Jenkins, 1977; Fogel, 1982; Davila, 1986 and Borjas, Freeman and Lang, 1987). Recent studies concentrating on apprehensions data from the Immigration and Naturalization Service (Bean, et al., 1990 and Espenshade, 1990 and 1995a as well as another study by Crane, et al., 1990) avoid many of the problems of previous efforts by converting apprehensions into border crossings by assessing the probability of getting caught and the population at risk of getting caught, thereby controlling for multiple apprehensions in the data (Passel, Bean and Edmonston, 1990). In order to gauge the influence of factors that affect flows across the border, these estimates rely on models with sets of demographic, economic, and behavioral variables (the size of young adult population in Mexico (15-34); the number of legalized SAWs; relative wage and unemployment ratios; dummy variables for months to capture seasonality; the number of officer hours and other measures of enforcement on the border for apprehensions) (Bean, et al., 1990).

Apprehensions data are limited because many unauthorized migrants are never apprehended, others may be apprehended many times, and the volume of

apprehensions depends on the amount of effort expended by INS to apprehend. Researchers compensate by using some measure of the amount of border patrol effort (Bean, et al., 1990; Jenkins, 1977; Fogel, 1982; and Borjas, et al., 1987) and include measures of the population at risk for apprehension (Bean, et al., 1990). Espenshade (1990, 1995a) takes the analysis one step further by using a repeated trials model that "captures the phenomenon that, once arrested by the U.S. Border Patrol and taken back across the Mexican border, most unauthorized migrants are likely to keep trying to enter the United States until they succeed" (Espenshade, 1990:175). Making use of INS data on the number of repeaters to estimate the probability of apprehension, and then using this to convert apprehensions measures to estimates of numbers of crossers, Espenshade constructs a time series on the monthly flow of unauthorized migrants. He arrives at an estimate for the period November 1986 to September 1988 of 175,000 per month, or a total of 4 million unauthorized migrants. In another repeated trials study, Massey and Singer (1995) utilize INS apprehensions data combined with data from a survey of migrants in Mexico. They arrive at an estimate of the net flow by 1989 of 5.2 million.

There are several assumptions that must be made to use apprehensions data in these models. The largest of these is that all individuals, even those apprehended and sent back across the border, will succeed by the end of the month. If some individuals do not attempt to cross again, this assumption will overstate the flow. In addition they rely upon the assumption that the probability of being caught is about 30 percent. A small change in this figure would change the size of the estimated flow. These studies assume that data on previous apprehensions is accurate and they assume that the probability of apprehension does not vary across groups (Passel, Bean and Edmonston, 1990). The model on repeated trials also relies largely on data on repeat crossers which depend on the facial recognition of the border crosser by border patrol agents, a process highly subject to error.

Issues Affecting Estimates

Lack of sufficient data in a number of areas makes difficult the interpretation of results of studies of the size and change of the unauthorized migrant population. These include: (1) insufficient evidence about the extent of underenumeration in official census and survey data of the unauthorized migrant population; (2) insufficient data to develop more accurate estimates of the size of the legally resident population to use in residual estimation approaches; (3) insufficient information and data about duration of stay in the United States among unauthorized migrants; (4) insufficient data to estimate emigration in the case of the legally resident immigrant population; and (5) insufficient evidence on the residency patterns of the SAWs population. In this section, we discuss the third of these issues and

introduce new evidence on the fifth. The first is discussed in a separate accompanying technical appendix entitled "Estimating Underenumeration among Unauthorized Mexican Migrants to the United States: Applications of Mortality Analyses," and the second and fourth are discussed in a separate accompanying technical appendix entitled "Issues in Estimating Legal Immigration."

Duration of Stay Issues

The distribution of the length of duration of stay in the United States among unauthorized migrants by mode of entry and the change in this distribution over time are crucial factors in understanding the significance of various estimates of the size of the unauthorized migrant population. If almost all EWIs were circular migrants staying only a short time, and if almost all visa overstayers returned to their countries of origin within a couple of years or so, the policy significance of unauthorized migration would be greatly different than if either EWIs or visa overstayers, or both, contained substantial fractions of long-duration migrants. Similarly, long-duration migrants (say those who stay 10 to 20 years or more) but who then return to their countries of origin are different yet again in their implications for policy from migrants who stay permanently.

At present, very little is known about the distribution of duration of stay of EWIs and visa overstayers (although data on this variable are now available for the subgroup of EWIs who have returned to Mexico from the studies conducted by Massey and his colleagues). Also, information on the duration of stay of visa overstayers has reportedly been calculated but not released by the INS. One of the reasons duration information is important is because different duration migrants exert different demands on public benefits. At the extremes, if the flow of EWIs and visa overstayers were each very large, the stock of unauthorized migrants in the United States at any one point in time would be sizable even if all durations of stay were relatively short (i.e., even if all migrants were temporary). If EWIs were to exhibit typically longer durations than visa overstayers, they would contribute more to the stock of unauthorized migrants on that count alone.

What does the available evidence suggest about the comparative distributions of duration of stay among EWIs and visa overstayers? In the case of EWIs, almost all of whom are from Mexico, several pieces of evidence point to increasing durations of stay over the past 15 to 20 years: (1) increasing proportions of entire families, including women and children in the Mexican flow (Bean, et al., 1990; Woodrow and Passel, 1990; Cornelius, 1992); (2) apparently decreasing rates of underenumeration of the unauthorized Mexican-born population in official U.S. Censuses and surveys, as noted above, a trend that could result from increasing proportions of migrants with long durations of stay, especially given that census

undercount rates in general have not been declining over the same period (Robinson, et al., 1993); and (3) ethnographic studies whose results indicate that Mexican migrants now embarking for the United States show longer intended durations of stay than prior migrants (Cornelius, 1992). Unless a comparable shift has occurred in the duration distribution among overstayers, this would have the effect of raising the proportion of the unauthorized stock attributable to EWIs. In the case of visa overstayers, the only relevant evidence to our knowledge is Warren's (1995) finding that when overstayers were traced for a year or two longer than the one year that is typically examined for purposes of defining an overstay, about 46 percent had either converted their status or returned to their country of origin. This suggests that if they were followed a bit longer, the vast majority would be found to have converted their status or returned.

Even though durations of stay may be increasing among EWIs, many may eventually return to Mexico (a pattern we might term long-term circular migration). Evidence of this pattern would also have significant policy implications. Tables 4 to 6 present information on the extent of cohort succession among Mexican-born persons based on results from the 1970, 1980, and 1990 U.S. Censuses and the 1994/95 CPSs. Does the evidence in these tables indicate that Mexican migrants tend to return to Mexico after having spent time in the United States, a phenomenon we would expect to be more likely among unauthorized migrants? Because there were hardly any unauthorized migrants enumerated in the 1970 Census, we would not anticipate evidence of cohort attrition beyond what we would expect based on mortality in the 1980 data, and this is in fact what we observe. In the cases of 1990 and 1994/95 data, however, evidence of substantial cohort attrition emerges. Since there is no known reason to think this occurs because of migration to some country other than the United States, it is reasonable to think it stems at least in part from return migrations to Mexico among persons in their late forties and fifties. This phenomenon, of course, would reduce the stock of Mexican EWIs compared to the case where long-term circular migration did not occur and most migrants were permanent.

SAWs Residency Patterns

The number of SAWs resident in the United States or Mexico is a crucial element in developing residual estimates, as noted above. To develop a rough estimate of the number of SAWs living in Mexico at any single point in time during the early 1990s, we used data from the Mexican Migration Project (1996) that collected interviews on households in 39 communities in Mexico with a smaller sample of households in the United States. The households in the Mexican sample were drawn from simple random samples of households in the 39 communities. The households

in the United States were drawn from a non-random sample of 10-20 out-migrants from the Mexican communities (none of the U.S. data was used for estimating SAWs). We selected only those migrants in Mexico who reported that they came to the United States under the Agricultural Workers Program (SAWs). The interviews with this subsample of respondents were conducted between 1987 and 1995. Of the 236 SAWs in the data, 191 were interviewed in Mexico. These 191 cases were then classified by state of residence in Mexico. The number of households sampled in the state and the number of household in the state from the 1990 Mexican census (INEGI, 1990) were used to calculate the proportion of households in each state that were included in the sample. The number of SAWs by state was divided by this sampling fraction and summed across states to arrive at the total number of SAWs living in the Mexican states. Finally, three estimates of the number of SAWs living in Mexico were developed assuming different proportions of migrants from Mexico coming from the seven sampled states. These estimates assume that 25%, 33% or 40% of all migrants from Mexico to the United States come from these seven sending states. The results are presented in Table 7 and indicate that about 240,000 to 380,000 SAWs were resident in Mexico at a single point in time during this time interval. Since 1,050,000 of the SAWs were from Mexico, 670,000 to 810,000 of the SAWs are estimated to have been resident in the United States at any single point in time during the early 1990s.

Summary of Results from Estimating Procedures

As of 1980, stock and flow estimates of the unauthorized migrant population tended to be unreliable due in part to lack of methodologies for correcting for biases in the available data sources. For instance, better methods had to be developed in order to make more valid estimates of in-flow on the basis of INS apprehensions and nonimmigrant entrance/exit forms. Also, early analytic estimates tended to be inconsistent in their assumptions, methodologies, and, consequently, in the populations they described. Hence, the various estimates were difficult to compare and evaluate (Bos, 1984). Finally, reviewers (Siegel, et al., 1980; Hill, 1985) found that most early analytic estimates of stock and flow were highly sensitive to their underlying assumptions. More complete data about the foreign-born and the unauthorized migrant population had to be obtained in order to better support underlying assumptions, such as those made about undercount (Goldberg, 1974; Heer, 1979) and death rates (Robinson, 1980). As a result of these and other problems, Siegel and his co-authors concluded in 1980 that “there are currently no reliable estimates of the number of unauthorized residents in the country or of the net volume of unauthorized immigration to the United States in any past recent period”

Table 7
Estimated Number of SAWs Living in Mexico

Mexican State	Number of Hogares	Hogares in Sample	% of Hogares in Sample	Number of SAWs in Sample	Estimated Total SAWs
Jalisco	1,038,000	901	0.087	18	20,736
Guanajuato	703,000	800	0.114	17	14,938

Colima	88,000	200	0.227	1	440
Total				191	95,509

Estimated Number of SAWs Living in All of Mexico
If 25% of migrants come from above states 382,040
If 33% of migrants come from above states 286,530
If 40% of migrants come from above states 238,775

Sources: 1990 Mexican Census; Mexican Migration Project (1996).

(1980). Nevertheless, they conceded that the analytic studies supported the view that by the end of the 1970s, 2.5 to 5 million unauthorized migrants and 1.5 to 2.5 million unauthorized Mexican migrants resided in the United States.

The residual studies conducted during the 1980s (see Table 8) obtained results at the beginning of the 1980s that tended toward the lower end of this range, subject of course to considerable uncertainty about the fraction of the unauthorized Mexican migrant population not enumerated in the official U.S. Censuses and surveys on which they were based. The results of these studies also showed the effects of IRCA's legalization programs, which removed substantial numbers of unauthorized migrants from the estimates of stock. They also revealed that the unauthorized migrant population (both overall and from Mexico) continued to grow annually during the 1980s, diminished in total numbers only by the legalization programs of IRCA. By 1992, the INS reported that 3.4 million unauthorized migrants overall

and 1.3 million from Mexico resided in the country, totals that have subsequently been updated to 5.0 million and 2.7 million by October 1996 (U.S. Immigration and Naturalization Service, 1997.

Two broad classes of considerations affect the significance of these (and in fact any) estimates. One, of course, is their accuracy. To what degree can we be confident that the figures reflect the sizes of the populations they are intended to represent? While uncertainties remain (as noted in discussions above), there is no question that the results of research on the magnitude of stocks and flows during the 1980s has narrowed considerably the range of plausible estimates. However, because of data gaps (e.g., the deletion of I-53 registration system, inadequate information on emigration, and the other issues noted above), estimates during the

1990s that rely on residual approaches may be subject to increasing uncertainty, and thus perhaps are increasingly likely to generate broad ranges of estimates (Woodrow-Lafield, 1996).

A second factor that affects the significance of estimates is the context in which they occur. Estimates are most appropriately viewed not in isolation, but in relation to other kinds of changes, including population changes. We discussed above the policy significance of possibly shifting proportions of EWIs and visa overstayers. More broadly, it is of interest to examine how the estimates of unauthorized Mexican migration compare to population size generally in both the United States and Mexico. The estimated enumerated unauthorized Mexican population (1.131 million) in 1980 represented about 51 percent of the total Mexican-born population in the United States, 8.0 percent of the U.S. foreign-born population, 12.9 percent of the total Mexican-origin population, 0.4 percent of the total U.S. population, and 1.7 percent of the total Mexican population (see Table 9).

What evidence is there about the size of the unauthorized Mexican migrant population during the 1990s? Estimates of Mexican unauthorized migrants should readily square with evidence about (1) the overall size of the Mexican-born population in the United States, (2) estimated rates of underenumeration in the legal unauthorized populations, and (3) estimates of the size of the legal Mexican-born

Table 9
Relative Size of the Unauthorized Mexican Migrant Population Expressed as a Percentage of the Mexican and the United States Foreign-born, Mexican-origin, and Mexican-born Populations, 1980–1996

Size of Unauthorized Mexican Migrant Population As a Percentage of:	1980	1990	1996
U.S. Population	0.5	0.5	1.1
Mexican Foreign-born	51.4	30.7	49.9
Foreign-born	8.0	6.7	13.4
Mexican Origin	12.9	9.9	15.3
Mexican Population	1.7	1.6	3.1

Notes: Estimates of enumerated authorized Mexican migrant population are: 1980, 1,131,000 (Warren and Passel, 1987); 1990, 1,321,000 (Warren, 1995); 1996, 3,100,000 (constructed by the authors).

population. A figure for unauthorized Mexican migrant stock may be constructed by starting with the overall size of the enumerated Mexican-born population from the March 1996 CPS of 6.68 million. Following the evidence from Hogan and Robinson (1993) and Van Hook and Bean (1997), we set plausible underenumeration rates for the legal and unauthorized Mexican populations at 4.0 and 12.0 percent respectively. Consistent with the evidence that about 700,000 SAWs were in the United States in the 1990s, we also adopt a mid-range estimate of 4.8 million legal Mexican immigrants (Woodrow-Lafield, 1997). Given these values, the *enumerated* number of legal immigrants is estimated as 4.608 million (4.8 x 0.96 = 4.608) and the number of unauthorized immigrants as 2.35 million (6.679 – [4.8 x 0.96]/ 0.88 = the number of unauthorized migrants = 2.35). Placing a 90 percent confidence interval around the overall total of 7.15 million (obtained by adjusting for undercount) adds and subtracts about 150,000 from each side of this value, giving an estimated range of 7.0 to 7.3 million total Mexican-born persons in the United States. In 1996, then, the figure of 2.35 million unauthorized Mexican-born migrants represents 37.8 percent of the U.S. Mexican-born population, 10.2 percent of the U.S. foreign-born population, 11.6 percent of the Mexican-origin population, 0.8 percent of the total U.S. population, and 2.3 percent of the Mexican population (see Table 9).

Note

1. The Census Bureau estimate is not 0.728 million larger than the Clark, et al., estimate, but only 0.415 million larger because of differences in assumptions other than those related to the residence of the SAW population.

QUANTIFICATION OF MIGRATION

Estimating Underenumeration among Unauthorized Mexican Migrants to the United States: Applications of Mortality Analyses

Jennifer Van Hook & Frank D. Bean

Because residual techniques generate estimates of the *enumerated* portion of the unauthorized Mexican population, they underestimate the true size of the unauthorized population at any point in time by an amount equal to the size of the unenumerated portion of the population. In order to develop estimates of the total size and growth of the unauthorized Mexican population, it is thus important that methods be developed for assessing the size and growth of the *unenumerated* portion of the population. A number of researchers have made and continue to make assumptions about the underenumeration rate for the unauthorized migrant population that are not substantially empirically based. For instance, some have argued that the undercount rate for unauthorized migrants must be at least as high as the highest rate among native-born groups. On the basis of this logic, some analysts argue that undercoverage must be as high as 20 percent, the rate exhibited by native-born African-American males (e.g., Passel, Siegel, and

Robinson, 1982). Others have argued that the undercount rate in the 1990 Census may be at least as high as it was in the 1980 Census (Woodrow, 1991). However, if the unauthorized migrant population were more settled and less concentrated in agricultural occupations in 1990 than in 1980, then the undercount rate in 1990 might be lower than it was in 1980.

Evidence about the size of the unenumerated portion of the unauthorized population for the census years 1980 and 1990 has been obtained by employing one of two different approaches. The first involves direct attempts to estimate first the undercount rate through comparisons of U.S. Census results with external data about small or localized populations, such as school enrollment records, in-depth survey results, and the findings from ethnographic field research. Estimates of the rate of undercount are then applied to the estimates of the size of the unauthorized population enumerated in the Census in order to approximate the size of the entire unauthorized population. The second approach entails first making independent assessments of the entire unauthorized migrant population or national origin groups within the population based on data sources and methods that are thought to be less sensitive to undercount, and then comparing these estimates with the enumerated population in order to estimate the rate of undercount. The results of both of these approaches are reviewed below, first with respect to the 1980 Census enumeration and then the 1990 Census enumeration.

Direct examinations of the level of undercount indicate that between 20 and 50 percent of the stock of unauthorized residents appeared to be missing from the 1980 Census enumeration. One study compared Los Angeles public school enrollments with estimates of families with school-aged children in the 1980 Census (Muller and Espenshade, 1985) (see Table 1). The results indicated that nearly all families in Los Angeles were enumerated, including families of unauthorized migrants. These results are consistent with the observation that the census is better at enumerating settled populations such as unauthorized migrant families than single migrants. The results of the study also suggested that the undercount rate of the entire unauthorized population was probably no greater than 50 percent. This view was substantiated by the results of a survey of Mexican adults living in Los Angles County (Heer and Passel, 1985, 1987). Foreign-born respondents were asked whether they were legal residents and if so, to show the interviewer their “Green Card” or equivalent evidence of legal status. Foreign-born respondents who indicated they were undocumented or failed to show evidence of legal status were enumerated as unauthorized migrants. Comparisons of the results of the survey with the number of unauthorized Mexican migrants enumerated in the 1980 Census (Passel, 1985) suggested that the undercount rate among Mexican unauthorized migrants was probably no greater than about 44 percent (Passel, 1985; Passel and Robinson, 1988) (See Table 2).

Table 1
Studies with Implications for Underenumeration

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
Bean, King, and Passel (1983)	1980	Mexican unauthorized migrants	Sex-ratio, age distribution assumptions Data: Mexican Census	1.5 - 3.8 million (no more than 4 million)

[a]Implied population based on estimate of undercount (see note below).

[b]Implied undercount rate based on estimate of population (see note below).

Note: The implied population and undercount rates are based on the assumption that 2.1 million unauthorized migrants (1.1 million unauthorized Mexicans) were enumerated in the 1980 Census, and that 2.4 million (1.9 million Mexicans) were enumerated in the 1990 Census.

Indirect evidence of undercoverage suggests a narrower range of undercount for the unauthorized population, falling roughly between 30 and 40 percent. As noted above, Bean, King, and Passel (1983) attempted to estimate the number of Mexicans who had emigrated to the United States by analyzing the age and sex composition of the population enumerated in the 1980 Mexican Census. Due to uncertainties about the patterns of undercount in the Mexican Census and the age-sex composition of the emigrant population, Bean, et al. (1983) concluded

that the number of unauthorized Mexicans living in the United States could be as low as 1.5 and as high as 3.8 million. Comparing this range with the number enumerated in the 1980 U.S. Census—1.131 million (Warren and Passel, 1987)—the Bean, et al. (1983) estimate implies an undercount between 25 and 70 percent. However, residual estimates of the Mexican unauthorized population enabled researchers to narrow the range of assumptions used in this analysis (Bean, King, and Passel, 1986; Passel, 1985; Passel and Robinson, 1988). The results of these revisions indicated that there were probably as few as 1.5 to 1.9 million unauthorized Mexicans migrants in 1980. Assuming that Mexicans comprise about 60 percent of the unauthorized population, this suggests that between 2.5 and 3.2 million unauthorized migrants were living in the U.S. in 1980. A comparison of these estimates with the approximation of the enumerated unauthorized population suggests an undercount rate of 25 to 40 percent among Mexicans and 18 to 36 percent among all unauthorized migrants.

Using a different approach, Borjas, Freeman, and Lang (1991) analyzed vital statistics data to determine the number of unauthorized immigrants missed in the 1980 Census. The method they used is similar to that used by Robinson (1980), except that it yields more precise results because it employs data on the number of deaths to Mexican-born persons residing in the United States (such data became available in 1984 when vital statistics began to record place of birth on death certificates). The methodology used by Borjas, Freeman, and Lang rests on the assumption that (1) all deaths to unauthorized and legally resident Mexican-born persons that take place in the United States are recorded in the U.S. vital statistics and (2), that the Mexican-born population experiences age specific death rates that are quite similar to those experienced by the U.S. native-born population. If these assumptions hold, then the total Mexican-born population living in the United States may be approximated by dividing the number of deaths to Mexican-born persons by the death rate. By comparing this estimate with the number of Mexican-born persons enumerated in the 1980 Census, the number of unenumerated Mexican-born persons can then be estimated. Borjas, Freeman, and Lang's results indicate that the number of unenumerated unauthorized Mexicans in 1990 was about 800,000. They add this to Warren and Passel's estimate to yield a total of 1.9 million unauthorized migrants from Mexico, which implies a 40 percent undercount rate. The results of this method tend to be highly sensitive to the underlying assumptions. Nevertheless, if the effects of its limitations could be minimized, the method has potential because it is empirically based, it can provide national level results, and it can be used to obtain annual estimates of the unauthorized population by age, sex, and country-of-origin, as we demonstrate below in an application to the 1990 Census enumeration of unauthorized Mexican-born male and female migrants.

To summarize, the results of undercount studies as well as comparisons of external estimates with estimates of the enumerated unauthorized population suggest that at least 60 percent of unauthorized residents were enumerated in the 1980 Census. This implies that there were at most about 3.4 million unauthorized migrants and 1.9 million unauthorized Mexican migrants living in the United States in 1980.

In the case of the 1990 Census enumeration, both direct and indirect evidence suggest that the undercount rate for the unauthorized migrant population was lower than it was in 1980. The direct evidence comes from a series of ethnographic studies conducted by researchers working with the Census Bureau. The main purpose for conducting these studies was to gain qualitative information about the causes of undercount, although the results of the research can also be used to shed light on undercoverage rates among various populations. The ethnographic evaluations were conducted in 29 different neighborhoods across the United States and Puerto Rico, each of which contained about 100 households. These 29 neighborhoods were selected because they were thought to contain large concentrations of difficult-to-enumerate populations. Experienced ethnographers made an effort to become familiar with the households and household members who lived within the sample area by accessing informal networks and gaining information about the actual residences of people. Their assessments of the numbers of residents were compared with the official Census counts for the sample areas. The results of the comparisons showed that, among those living in areas containing large concentrations of unauthorized migrants,[1] the undercount rate was *at most* 25 to 30 percent. One area, Long Island, had an undercount rate as high as 72 percent, but this result was not typical. The other areas showed undercount rates as low as or lower than 28 percent, and five areas had undercount rates less than 18 percent (U.S. GAO, 1993; de la Puenta, 1993).

Indirect evidence of the undercoverage of the unauthorized population in 1990 comes from only a few studies. Although Warren (1995) produces estimates of the entire unauthorized population in 1990, his estimates appear too low and cannot be relied upon. For instance, he puts the total Mexican-born unauthorized population at 1.0 million, which is 92 percent *lower* than the residual estimate for 1990 (U.S. GAO, 1993). Woodrow (1991) makes a "point estimate" of the unauthorized population in 1990 of about 3.3 million. Woodrow (1991) constructs this estimate by projecting forward the estimated 1980 unauthorized population to 1990, adjusting for net growth during the 1980s and legalizations due to the amnesty provisions of IRCA.

Another study showing indirect evidence of the undercount rate in 1990 was conducted by U.S. GAO (1993) in consultation with Corona Vasquez (1991). By comparing the Mexican population enumerated in the Mexican Census in 1980

with those enumerated in the 1990 Mexican Census, Corona Vasquez (1991) estimated that 1.5 to 3 million Mexicans emigrated during the decade. By adjusting this estimate for differential undercount and legal migration to the United States, GAO (1993) concluded that about that about 2.7 million unauthorized Mexicans were present in the United States in 1990. Assuming that Mexicans comprise about 80 percent of the total unauthorized migrant population (based on the 1989 CPS residual estimates), GAO puts the total unauthorized migrant population at 3.4 million. Like the results obtained from the ethnographic studies, the Woodrow (1991) and GAO (1993) estimates imply an undercount rate of about 30 percent. This level of undercoverage implies an unauthorized population of about 3.4 million (2.7 million Mexican unauthorized migrants) in 1990.

In what follows, we apply the "death registration" method used by Borjas, Freeman, and Lang (1991) to obtain another estimate of the total unauthorized Mexican population and the underenumeration rate for 1990. One of the drawbacks of the death registration method is that it is sensitive to its underlying assumptions. Nevertheless, if the data used to produce the final estimates were more carefully selected so that confidence in the underlying assumptions was greater, then the method could be used to obtain annual estimates of the total size of the unenumerated unauthorized population by country of origin. In the section below, we describe the method in greater detail and evaluate its underlying assumptions. Then, using a range of plausible initial assumptions, we estimate likely ranges for the undercount rate for the 1990 unauthorized Mexican migrant population.

Methodology

On the assumption that all deaths to Mexican-born persons living in the United States are recorded as such in the U.S. vital statistics and that an appropriate and supportable assumption about the death rate experienced by the Mexican-born population can be made, then the number of Mexican-born persons living in the United States by age and sex (L_x) can be estimated by dividing the number of deaths to Mexican-born persons living in the United States (d_x) by the death rate experienced by the population (m_x):

$$L_x = d_x/m_x$$

where x indexes age and sex groupings (Borjas et al., 1991). The population estimate L_x is an estimate of the person-years lived during the year and only approximates the population at the time of the census enumeration. By subtracting the number of Mexican-born persons enumerated in the census (C_x) from the estimated population (L_x), we can then estimate the size of the unenumerated portion of the Mexican-born population (U_x):

$$U_x = L_x - C_x$$

If most legally resident Mexican-born persons are enumerated in the Census, then it can be assumed that most of the unenumerated population, U_x, consists of unauthorized persons. Thus, the total unauthorized population, T, can be estimated as the sum of the unenumerated population, U (that is, U_x summed across all x's), and the estimated enumerated unauthorized population, I; and the undercount rate can be estimated as U/T.

Underlying Assumptions

Number of Deaths (d_x)

First, the quality of the estimates depend on the extent to which deaths to Mexican-born persons that take place in the United States are recorded in U.S. vital statistics, and further, that the U.S. vital statistics correctly identify place of birth. It is reasonable to assume that the vast majority of deaths to foreign-born persons are recorded in U.S. death records. As others have argued, it would be very difficult, and there would be little motivation, to "hide" the death of a foreign-born person living in the United States (Borjas et al., 1991). Even among infants whose mothers had illegally crossed the border to give birth, very few infant deaths would go unrecorded because the vast majority of births to unauthorized migrants take place in hospitals (Forbes and Frisbie, 1991).

However, even if all deaths to foreign-born persons are recorded in the U.S. vital statistics, place of birth of some foreign-born persons may be misrecorded as U.S.-born on their death certificates. Unfortunately, little is known about the quality of data about place of birth on death certificates. However, some evidence suggests that Hispanic ethnicity is inaccurately recorded on about 20 percent of infant (Hahn, Mulinare and Teutsch, 1992) and seven percent of adult death certificates (Sorlie and Johnson, 1992). Place of birth is likely to be more accurately recorded than ethnicity because place of birth is easier to define, is not complicated by mixed parentage, and does not depend on perceptions of self-identity (for a discussion on the difficulties in measuring race/ethnicity in death data, see Hahn and Stroup, 1994). Borjas, Freeman and Lang (1991: 81) similarly argue that the error associated with misreporting place of birth is likely to be small: "While there may be some tendency for friends and relatives of unauthorized aliens to disguise country of origin, the head of Registration of Methods of the Public Health Service informed us that in his opinion these records are no less accurate for unauthorized aliens than for other groups, leading us to discount this potential source of error."

In making estimates of the unenumerated Mexican-born population, we assume the error associated with inaccurate reporting of place of birth to be no

greater than five percent. Hence, we employ two alternative sets of estimates of the number of deaths of Mexican-born persons. The first, labeled "D1" in Table 3, is the number of deaths to Mexican-born U.S. residents recorded in the U.S. vital statistics. The second, labeled "D2," is the recorded number of deaths inflated by five percent.

Mortality Schedule (m_x)

The validity of the estimate also depends on the extent to which the age- and sex-specific death rates used in making the estimate (m_x) conform to the actual mortality schedule experienced by the Mexican-born population. Unfortunately, there is a great deal of uncertainty about the mortality schedule of this population because of uncertainty in estimates of the population at risk of dying. Borjas, Freeman and Lang (1991) assume that the Mexican-born population experience the same or higher age-specific death rates as the entire U.S. population, and therefore use its mortality schedule for making their estimates. However, evidence exists that there are significant differences between the mortality schedules of the total U.S. (dominated by non-Hispanic whites) and Hispanic origin populations. Estimates made in the United States and Healthy People 2000 Review (U.S. Department of Health and Human Services, 1992) indicate that Hispanic males aged 15 to 44 have age-specific death rates that range from 15 to 24 percent higher than non-Hispanic whites, and Hispanic females and Hispanic males older than 44 have rates that range from 9 to 32 percent lower. These estimates are unlikely to be strongly biased due to uncertainty in the size of the population at risk of dying because they closely correspond with other estimates that are not affected by this type of error. In an analysis of data obtained from the National Longitudinal Mortality study, in which approximately 115,000 men and women age 15 to 24 were interviewed and then followed up five years later, Singh and Yu (1996) found that Hispanic men and women age 15 to 24 experience mortality levels that are nearly identical to (about 96 percent of) those reported by the United States and Healthy People 2000 Review.

One potential source of error in the estimates made in the United States and Healthy People 2000 Review is that the number of deaths to persons of Hispanic origin could be underestimated due to inaccurate recording of ethnicity on death certificates. As discussed above, this error has been found to be as large as seven percent. We use three different mortality schedules in making alternative estimates of the number of unenumerated Mexican-born persons living in the United States in 1990. The first mortality schedule, labeled "M1" in Table 3, is that experienced by the white population. The second, labeled "M2," is the mortality schedule of Hispanics as it is reported in the United States and Healthy People 2000 Review.

Table 3
Underlying Assumptions Used in Estimates of the Mexican-born Unenumerated Population, 1990

		Deaths to Mex. Born		Death Rate, 1990			Enumerated Mex. Born	
		(D1)	(D2)	(M1)	(M2)	(M3)	(C1)	(C2)

	35-44	293	308	.0012	.0011	.0012	344,507	369,850
	45-54	419	440	.0032	.0023	.0024	192,755	211,313
	55-64	674	708	.0082	.0059	.0063	109,420	127,744
	65-74	1,122	1,178	.0195	.0146	.0156	63,470	144,398
	75-84	1,951	2,049	.0494	.0352	.0376	40,698	52,452
	85+	2,098	2,203	.1554	.1082	.1158	14,957	15,623
	SUM	7,117	7,473				1,928,500	2,198,792

Note: Deaths include deaths to Mexican-born U.S. residents only

Finally, the third mortality schedule, labeled "B3," is the Hispanic schedule in which each of the age- and sex-specific death rates are inflated by seven percent in order to account for possible underreporting of Hispanic deaths.

Enumerated Mexican-born Population (C_x)

The estimates of the unenumerated population also depend on the extent to which Mexican-born persons who are enumerated in the 1990 U.S. Census correctly identify their place of birth. Warren and Passel (1987) calculate that

215,000 Mexican-born people misreported themselves as U.S. born in the 1980 Census. Woodrow (1991) estimates that by November, 1989, about 636,000 Mexican-born persons inaccurately reported as U.S. born in the CPS. To obtain this figure, Woodrow (1991) first estimated the total U.S.-born Mexican-origin population as 8,493,000 persons (a figure reached by projecting forward the estimate from 1980), and then she subtracted this figure from the number enumerated in the 1989 CPS.

In making our estimates, we employ two approximations of the total enumerated Mexican-born population. The first, labeled "C1" in Table 3, is the Mexican-born population as it is observed in the 1990 Census. The second, "C2," is the observed population adjusted upward for inaccurate reporting of place of birth. The "C2" population was arrived at by adding to the observed Mexican-born population an estimate of the number of people who reported themselves as U.S. born but who are actually Mexican born. The number of misreporters, in turn, was estimated as the difference between an independent estimate of the Mexican U.S.-born population (Woodrow's (1991) estimate projected forward from November, 1989 to April, 1990) and that observed in the U.S. Census.

Unenumerated Mexican-born Population (U)

Another assumption made by Borjas, Freeman, and Lang (1991) is that their estimate of the unenumerated Mexican-born population, U, consists entirely of unauthorized migrants. However, the legal Mexican-born population is likely to have age- and sex-specific underenumeration rates that are at least as high as those among non-Hispanic whites. Therefore, the unenumerated portion of the population would consist of both legal and unauthorized Mexican-born persons. Accordingly, we subtract from our estimate of U (i.e., the sum of U_x) the approximate number of unenumerated *legal* Mexican-born persons.

We approximate the unenumerated legal population in the following way. Several researchers have put the 1990 enumerated unauthorized population at about 2.4 million (Woodrow, 1991; GAO, 1993; Clark, et al., 1994). We approximate the Mexican component of the 1990 unauthorized population as proportional to the relative sizes of the Mexican-born and total unauthorized population enumerated in the 1989 CPS, such that the Mexican-born unauthorized population in 1990 is estimated at 1.908 million. The remaining enumerated Mexican-born population (including those who misreported as U.S.-born), numbering 2.960 million, is classified as legally resident. We then allocate the legal and unauthorized Mexican-born populations into age- and sex-categories by assuming that the unauthorized population has the same age and sex composition as Mexican-born, non-citizen, post 1982 arrivals. Finally, we apply the age- and sex-specific

undercount rates of the white population (Robinson et al., 1993) to our approximation of the legal population. As a result of this procedure, we estimate that about 34,160 legal Mexican-born males (2.1 percent) and 5,249 females (0.4 percent) are missing from the 1990 Census. Accordingly, we subtract 34,160 from our estimates of the unenumerated male population, and 5,249 from the unenumerated female population.

Correspondence Between Person-years (L_x) and the Number Eligible to be Enumerated

In estimating the number of unenumerated Mexican unauthorized migrants, the death registration method compares an estimate of the person-years lived in the United States by Mexican-born persons (L_x) with the number of such persons enumerated in the census (C_x). This procedure relies on the assumption that L_x closely approximates the number of Mexican-born persons who were eligible to be enumerated in the census (that is, they were living in the United States on April 1, 1990). For this assumption to hold, all Mexican-born persons living in the United States on April 1, 1990 who subsequently die in 1990, must have died in the United States. If a significant number were to leave the United States after April 1, then their deaths would not be recorded in the U.S. vital statistics, and the estimates of L_x and U_x would be too low. U_x could even be negative if more people were counted in the census than were estimated based on the number of deaths. We expect that this would be most evident among older people because they are more likely to return to Mexico mid-year because of an illness or retirement. To minimize this type of error, we exclude estimates of U_x for the age-sex groups in which the estimate of U_x is negative from the sum total of the unenumerated population estimates. That is, when summing across all U_x's, only the positively valued estimates are included in the sum.

In addition, for the above assumption to hold, all deaths that take place in the United States to Mexican-born persons must be due to those who were living in the United States on April 1. If a significant number were to migrate to the United States after April 1 and subsequently die, then L_x and U_x would be overestimated. We expect that this would occur more often among those who work seasonally in the United States, such as working-aged men. Unlike the first type of error described above, which can be detected in part by negatively-signed estimates of U_x, this type of error is difficult to identify. Hence, we do not attempt to adjust our estimates to take into account this kind of discrepancy. Rather, we simply note that this type of phenomenon is likely to lead to overestimates of the number of unenumerated Mexican-born persons living in the United States at the time of the U.S. Census.

1990 Estimates

We produce a series of estimates of the number of unenumerated unauthorized Mexican-born persons living in the United States in 1990. An estimate is made for each combination of the assumptions regarding the numbers of deaths, different mortality schedules, and sizes of the enumerated Mexican-born population. Since we employ two alternative estimates of the number of deaths, three alternative mortality schedules, and two alternative enumerated populations, we make a total of twelve estimates (2 x 2 x 3 = 12).

Table 4 illustrates how one such estimate is constructed. In this example, the unadjusted number of deaths to Mexican-born persons (D1), the mortality schedule experienced by white men and women (M1), and the unadjusted enumerated Mexican-born population (C1) are used to construct the approximation. The first and second columns show the number of deaths (d_x) and the age- and sex-specific death rates (m_x), respectively. Dividing the number of deaths by the death rate, we obtain the third column, an estimate of the total Mexican-born population in 1990. The fourth column displays the enumerated Mexican-born population (C_x), and the final column shows the difference between the total and enumerated population estimates, that is, the unenumerated Mexican-born population (U_x). As expected, the estimates of U_x tend to be negative at the older ages, particularly among males. Summing across the positive values, we obtain an approximation of 686,952 unenumerated males and 173,068 unenumerated females. When we subtract the estimated number of unenumerated legal migrants from these figures, we obtain estimates of approximately 653,000 unenumerated unauthorized males and 168,000 unenumerated unauthorized females. If we assume an enumerated unauthorized migrant population of 1.9 million (1.1 million males, 0.8 million females), then these estimates imply an underenumeration rate of about 37 percent among males, 17 percent among females, and 30 percent among both sexes combined.

Table 5 presents estimates of the unenumerated unauthorized Mexican-born population, the total unauthorized population, and the implied undercount rate for each of the twelve combinations of underlying assumptions. The estimates of the total unauthorized Mexican migrant population range 2.1 to 2.9 million, with the interquartile range spanning 2.2 to 2.6 million. The undercount rates corresponding with the interquartile range of estimates ranges from only 14 to 26 percent. Even the highest estimate of 2.9 million unauthorized migrants implies an undercount rate of only 34 percent. The estimates of the underenumeration rate are higher for males, among whom as many as 40 percent may not have been enumerated. Finally, we note that of the three underlying assumptions, those pertaining to the mortality schedule and the enumerated population tend to exert the greatest influence on the estimates.

Table 4
Example of an Estimate of the Unenumerated Mexican-born Population, 1990
(Using Underlying Assumptions D1, M1, and C1)

	Age	Deaths (D1)	Death Rate (M1)	Total Pop'n (Person-Years) (L) = D1/M1	Enumerated Population (C1)	Unenum. Population (U) = L - C1

See Table 3 on page 561 for various estimates of the number of deaths, mortality schedules, and the enumerated population.

In conclusion, the death registration method produces estimates of the underenumeration rate that correspond with other evidence about undercount. Namely, the underenumeration rate for unauthorized Mexican migrants in 1990 appears not to be as high as it was in 1980, most likely is no greater than 35 percent and may even be as low as 15 to 25 percent. In addition, the results corroborate other evidence that the female unauthorized migrant population is better represented in the U.S. Census enumeration than the corresponding male population. Nevertheless, the results also show that the death registration method produces estimates that are highly sensitive to their underlying assumptions. Although the method has a great deal of potential for use in the future, the quality of the estimates could be greatly improved if better information about the mortality rates experienced by the foreign-born population and the enumerated population were available.

Note

1. These were nine areas located in Long Island, rural Marion County, Oregon, Houston, Bronx, San Diego, San Francisco, Miami, rural Santa Barbara County, and New Orleans.

Quantification of Migration

The Mexican-origin Population of the United States in the Twentieth Century

Jennifer E. Glick & Jennifer Van Hook

The Mexican-origin population in the United States has grown substantially over the last century. It consists of several different components and the contribution of the Mexican-origin population to the size of the United States population has increased and continues to increase as a result of growth in each of these components. One part of this population consists of those individuals born in the United States who can trace their ancestry to Mexico. Another component consists of those individuals born in Mexico who have subsequently moved to the United States. The latter group (the Mexican-born population in the United States) can be broken down into three groups: naturalized citizens, legal immigrants and unauthorized migrants from Mexico. Our goal is to provide a general picture of both the past and present size, growth and distribution of the Mexican-origin population within the United States. The following focuses on changes in each group within this population. We begin by examining changes in the way this group has been measured over time. Since the United States Census is the primary source of this information, we focus on changes in these data. Next, we discuss the patterns of growth in the Mexican-origin population over the past century. Finally, we turn

to the potential for future growth and the geographic distribution of the Mexican-origin population in the United States.

Measurement of the Mexican-origin Population

"Ethnicity denotes a social identity deriving from group membership based on common race, religion, language, national origin, or some combination of these factors (Bean and Tienda, 1987: 38)." In part because ethnicity is a multidimensional concept, the way in which the Mexican-origin population has been defined by the United States Census Bureau has changed over the years, during which time Mexican ethnicity has been identified by a number of different indicators (see Table 1). Prior to 1970, Mexican ethnicity could be identified through the use of various objective markers, including place of birth, parents' place of birth, mother tongue, and Spanish surname. While serving well to identify Mexican-origin persons who were either foreign born or whose parents were born in Mexico, these identifiers failed to adequately identify third or higher generation Mexican-origin persons, especially those who no longer speak Spanish at home or who no longer have a Spanish surname due to intermarriage. These limitations are especially problematic for identifying the Mexican-origin population given the group's long history in the United States.

Table 1
Identifiers Available in the United States Census or Current Population Survey for the Hispanic Population, 1950–1996

Year	Birth-place	Foreign Parentage	Mother Tongue	Home Language Other than English	Spanish[1] Surname	Spanish Origin or Descent	Ancestry
1994-96	yes	yes	no	no	no	yes	no
1990	yes	no	no	yes	no	yes	yes
1980	yes	no	no	yes	yes	yes	yes
1970	yes	yes	yes	no	yes	yes	no
1960	yes	yes	yes [2]	no	yes	no	no
1950	yes	yes	no	no	yes	no	no

[1] Only available for five southwestern states.

[2] Available for 25% of the foreign-born population

In response to these concerns, a new measure of ethnicity was added to the 1970 Census in which Mexican ethnicity could be identified through the use of a subjective item, ethnic origin. The census measure of ethnic origin allowed respondents of any generation to identify themselves as having Mexican ethnicity. This measure was included in the 1980 and 1990 Censuses as well. Thus, measures of the size and distribution of the Mexican-origin population since 1970 depend on the ethnic self identification of individuals whereas measures in previous years rely upon the researchers' ethnic classification based on several indicators.

Size of the Mexican-origin Population: 1900–Present

Despite the many changes in the measurement of the ethnic composition of the United States, it is clear that the Mexican-origin population has grown steadily from 385,000 in 1910 to over 18 million in 1996, as demonstrated in Table 2. This

Table 2
Total Mexican-origin Population in the United States: 1900–1996

Year	Total Mexican-origin Population (in Thousands)	Percent of Total U.S. Population
1996	18,039 [1]	6.8
1990	13,393	5.4
1980	8,740	3.9
1970	4,532	2.2
1960	1,736 [2]	1.0
1950	1,346	0.9
1940	1,077	0.8
1930	1,423	1.2
1920	740	0.7
1910	385	0.4

[1] These figures are based on CPS data that are adjusted for undercount and thus are not comparable to census figures.

[2] Mexican-origin population calculated as a sum of the Mexican-born population and natives of Mexican parentage.

population nearly doubled in size in every decade except for the period from 1930 to 1960. Some of this growth in the Mexican-origin population can be attributed to natural increase of the U.S.-born population. Mexican American fertility rates are approximately 35 to 40 percent higher than those of Anglos (Bean and Tienda, 1987), while each of these groups appear to experience comparable mortality rates. Thus, even in the absence of migration, the Mexican-origin population would be expected to increase relative to the Anglo population.

Despite its relatively high rate of natural increase, the present day size of the Mexican-origin population in the United States is mostly attributable to immigration from Mexico during the twentieth century. Edmonston and Passel (1994) estimate that the Mexican-origin population would only have been 14% of its current size had there been no immigration from Mexico in the last 95 years. Moreover, the number of immigrants from Mexico living in the United States has been increasingly large both in terms of absolute numbers and in comparison to other immigrant groups. Table 3 presents the size of the Mexican-born population in the United States since 1900. The flow of immigrants from Mexico has fluctuated throughout the twentieth century but it is clear that this population has become an increasingly large component of the total foreign-born population in the United States. By 1996, 27.2 percent of immigrants living in the U.S. originated from Mexico.

Accompanying the growth in the stock of the Mexican foreign-born population in this century, is growth in the flow of immigrants arriving from Mexico. While the flow of immigrants has varied throughout the century, Mexican immigrants have become an increasingly large proportion of the total immigrant stream. Table 4 presents the number of Mexican immigrants arriving in the United States in each decade since 1900. Although the border between Mexico and the United States obtained its modern definition in 1848, records on the Mexican immigration to the United States were not kept until 1908. The accuracy of such data is dubious, moreover, because the border region at that time was largely unsupervised and the nature of immigration from Mexico at the very beginning of the twentieth century is unknown. Two of the border states (Arizona and New Mexico) were only territories under U.S. supervision until 1912.

Nevertheless, it can be seen that fluctuation in the growth of the Mexican-born population in the United States has been due to the political climate in the United States as well as economic demands for labor north of the border. The first large-scale increase in immigration from Mexico onto U.S. territory can be seen occurring between 1911 and 1920, during which time over 200,000 immigrants arrived from Mexico. Increased demands for labor brought about by the exclusion of Chinese workers in 1882, Japanese workers in 1907 and a shortage of European immigrants during World War I encouraged Mexican migration. Numbers of

[1] These figures are based on CPS data that are adjusted for undercount and thus are not comparable to census figures.

[2] Mexican-origin population calculated as a sum of the Mexican-born population and natives of Mexican parentage.

Mexican immigrants continued to increase as the federal government exempted the Western Hemisphere from the national quota laws of the 1920s and early 1930s in the name of Pan Americanism which was also encouraged by many in the southwest who looked towards Mexico for cheap labor (Reimers, 1992). During the 1920s, over 450,000 Mexican immigrants entered the United States, comprising 11.2 percent of the total immigrant in-flow. However, when the demand for jobs increased during the Great Depression of the 1930s, the United States repatriated many Mexican-origin individuals and the once high levels of Mexican immigration were greatly reduced.

Levels of immigration from Mexico once again increased to pre-1930s levels with the introduction of the Bracero Program from 1943-1964. Starting in World War II, non-Mexican farm workers in California sought higher paying jobs in the defense industry, reducing the available labor supply for farmers. This prompted growers to place pressure on Congress to admit temporary workers, or *braceros*,

Table 4
Immigration from Mexico to the United States: 1900–1995

Years	Number Arriving from Mexico in the Decade	Percent of All Immigrants Arriving in the Decade

[1] Numbers of those legalizing their immigration status from the *Statistical Yearbook of the Immigration and Naturalization Service* (1989–1995).

from Mexico. During the peak of the program in 1956, 445,197 workers were recruited (Reimers, 1992). Although these workers were expected to be temporary residents in the United States, many stayed along with their family members. While growers fought to retain the supply of cheap Mexican labor, Congress refused to extend the program beyond 1964.

Despite the end of the Bracero Program, both unauthorized and legal migration from Mexico has continued to grow during the past three decades. In particular, the numbers of Mexican immigrants admitted to the United States have recently increased dramatically, reaching 1.7 million or 22.6 percent of the flow in the 1980s and 1.5 million or 28.5 percent of the flow in just the first half of the 1990s. The size of the legal population increased dramatically during the late

1980s and early 1990s due to the amnesty provisions of the 1986 Immigration Reform and Control Act (IRCA). Under IRCA those unauthorized migrants who had lived in the United States since 1982 or who had been working in the United States in agriculture for at least six months were offered the opportunity to legalize their migration status. Numbers of those entering the United States are inflated because those legalizing their status under the IRCA provisions are included in these counts. Between 1989 and 1994, IRCA offered legal status to approximately 2 million unauthorized Mexican agricultural workers and other migrants who had been living illegally in the United States since 1982. Panel B of Table 4 illustrates the effect of the legalizations under IRCA on the size of the flow of immigrants from Mexico. When those legalizing their status under the amnesty provisions are removed from the official numbers of immigrants arriving in the decade, the size of the Mexican immigrant population entering between 1981 and 1995 is greatly reduced and is more comparable to the size of the flow during the 1970s.

The component of the Mexican-born population in the United States that receives the most popular attention is the unauthorized migrant population. While this segment of the Mexican-origin population in the United States is most visible in the media, its size is often debated because it is difficult to accurately evaluate. Table 5 presents the estimated size of the unauthorized Mexican migrant population from 1980 to 1996. The methods used to arrive at these estimates are presented in

Table 5
Examples of Various Estimates of the Unauthorized Mexican Migrant Population

Year	Est. Number of Unauthorized Mexican Migrants	Unauthorized Mexican Migrant Population as a Percentage of:			
		Total Foreign-born Pop'n	Mexican Foreign-born Pop'n	Mexican-origin Population	Total U.S. Population

[1] Estimate includes only the enumerated portion of the Mexican unauthorized population.

the separate appendix, "Issues in Estimating Unauthorized Migration to the United States." The estimated enumerated unauthorized Mexican population in 1980 was about 8 percent of the U.S. foreign-born population, 51 percent of the total Mexican-born population in the United States and about 13 percent of the total Mexican-origin population in the United States. By 1996, the unauthorized Mexican population had increased to represent nearly 11 percent of the foreign-born population in the United States, but was only 36 percent of the Mexican foreign-born population. Although unauthorized migration from Mexico continues, legal immigrants constitute by far the largest component of the Mexican-born population in the United States despite the attention given to unauthorized migrants.

The last component of the Mexican-born population in the United States are those immigrants who have become citizens of the United States. Table 6 presents the numbers of Mexicans who naturalized for selected years going back to 1960. Compared to other immigrant groups in the United States, Mexican immigrants have been slow to naturalize (Grebler, 1966; Bean and Tienda, 1987). There may be several factors influencing this comparatively low rate of naturalization but English language ability is frequently cited as the largest barrier to citizenship among Mexican immigrants (Reimers, 1992). It is clear from Table 6 that the proportion of Mexicans who are becoming citizens is increasing over time. Immigrants must reside in the United States for five years before becoming citizens of the United States. The number of immigrants becoming citizens is likely to increase substantially in the near future as those legalizing their status under IRCA become eligible for naturalization (Immigration and Naturalization Service, 1992).

Table 6
Number of Naturalizations among Mexican-born Persons in the United States: 1950–1996

Year	Number of Naturalizations Among Mexicans	Number per 10,000 Mexican-born Persons In the United States
1995	67,238	110.9
1990	17,564	40.9
1980	9,341	4.2
1970	6,195	0.8
1960	5,913	1.0

Projected Growth of the Mexican-origin Population

As the preceding discussion has illustrated, the Mexican-origin population in the United States has grown substantially over the last century and this group continues to make up an ever increasing proportion of the United States population. The growth of the Mexican-origin population is expected continue into the next century as well due to both natural increase and increased net immigration. According to the population projections made by the Census Bureau, the Hispanic-origin population will grow more in the next sixty years than all of the other racial and ethnic groups combined (Day, 1995). Table 7 presents the projections of the size of the Hispanic-origin population based on the U.S. Census projection from 1995. This projection assumes that the Hispanic population will have the highest annual number of immigrants entering the country than any other racial/ethnic group (350,000 annually). The Census Bureau projections are based on the assumption

U.S. Bureau of the Census, Current Population Reports, pp. 25-1130, U.S. Government Printing Office, Washington, D.C., 1996.

Projection of the Mexican-origin population constructed by the authors.

[1] Assuming that the proportion of the Hispanic population that is of Mexican origin remains the same as observed in 1990 (59.9%).

[2] Assuming the Mexican-origin population will continue to increase as a proportion of the total Hispanic population by 1.5 percentage points per decade.

that the Hispanic-origin population will continue to have higher fertility rates than other racial/ethnic groups. Fertility among Hispanics is currently matched only by Asians in the United States.

These projections indicate that the Hispanic-origin population will reach a size of 80.1 million by 2040, or nearly one quarter of the total U.S. population (Day, 1995). The last two columns of Table 7 present the population projection for the Mexican-origin population alone. Unfortunately, the Census Bureau does not make population projections for the Mexican-origin population separately from the entire Hispanic-origin population. Therefore, we adjust the Census Bureau projection for the entire Hispanic-origin population to approximate the projections for the Mexican-origin population. We make our projections by adjusting the Census projections based on the proportion of the Hispanic-origin population that is of Mexican origin. Two projections are presented each of which is based on slightly different assumptions. The first projection assumes that the proportion of the Hispanic populations that is Mexican origin will stay the same. The Mexican-origin population represented roughly sixty percent of the Hispanic-origin population in 1990. Our first projection for the Mexican-origin population, therefore, is made by simply taking sixty percent of the estimate for the entire Hispanic-origin population made by the Census Bureau. The second projection for the Mexican-origin population presented in Table 7 assumes that the Mexican-origin population will continue to increase as a proportion of the Hispanic-origin population over the next several decades.[1] Specifically, we assume that the Mexican-origin population will increase from 60 percent of the total Hispanic-origin population in the United States in 1990 to 67.4 percent of the Hispanic population in 2040. Based on either set of assumptions, the Mexican-origin population in the United States will more than double in size over the next sixty years. In fact, these projections indicate that the Mexican-origin population alone will be larger than the projected size of the Black population by the year 2040.

The projections presented in Table 7 make it clear that the Mexican-origin population in the United States will continue to increase for some time. However, there are other factors beyond natural increase that could alter the amount of growth of the Mexican-origin population. Changes in immigration or ethnic identity could affect future growth. For example, as those who legalized under IRCA become eligible for citizenship in the United States, they will also be eligible to petition to bring family members to this country (Immigration and Naturalization Service, 1992). Mexican immigrants have the largest pool of relatives who could become migrants to the United States under the family reunification provisions than any other foreign-born group in the United States (Schulte and Wolf, 1994). This factor would result in an even more rapid growth of the Mexican-origin population than was projected in Table 7.

Another source of change that could affect the projected size of the Mexican-origin population is changing rates of intermarriage and/or changing self identification among the children of mixed-ethnicity parents. The projections in Table 7 do not account for the possibility of changes in the patterns of exogamy. Intermarriage between racial/ethnic groups may alter the way future generations identify themselves given the present categories of race and ethnicity. Therefore, differential patterns of exogamy may alter the projected size of these groups (Bean et al., 1997). By 1990, 20.8 percent of Mexican-origin wives were married to non Mexican-origin husbands (Bean et al., 1997).

Edmonston, Lee and Passel (1994) have presented population projections adjusted for differential exogamy rates among Hispanics and other racial/ethnic groups. Increases in exogamy are built into their projections. Their estimates, presented in Table 8, show that the Hispanic-origin population in the United States could vary from between 50.9 million and 77.4 million people by 2040 depending on actual rates of exogamy. Table 8 also presents projections for the Mexican-origin population based on the same patterns of exogamy built into the Edmonston, Lee and Passel projections for the entire Hispanic-origin population. These projections demonstrate that, if the Mexican-origin population remains approximately 60% of the total Hispanic-origin population, individuals of Mexican origin will number

Table 8
Projected Size of the Mexican-origin Population in the United States Adjusted for Potential Exogamy: 1995–2040

	Hispanic-origin Pop'n (in millions)		Mexican-origin Pop'n (in millions)

[3] Both parents are of Mexican origin.
[4] At least one parent is of Mexican origin.

between 30 and 46 million by the year 2040 depending upon their rates of exogamy. These projections for the Mexican-origin population range as low as 63 percent of those Census Bureau projections that do not consider the affect of exogamy on the size of the Hispanic-origin population. Thus, these adjusted projections indicate that the Mexican-origin population may not grow as quickly as suggested by those projections that are not adjusted for differential rates of exogamy.

The Geographic Distribution of the Mexican-origin Population

In addition to its changing size and changing sources of growth, the Mexican-origin population has also experienced changes in its geographic distribution within the United States. Historically, the Mexican-origin population has been concentrated in the southwestern part of the country. Five states, Arizona, California, Colorado, New Mexico and Texas, contain the majority of the Mexican-origin population. The proximity of these states to Mexico made them a likely point of destination for immigrants. Mexican immigrants have been more geographically concentrated than their U.S.-born counterparts although both groups are more likely to be found in the Western or Southern States than other Hispanic groups. Whereas Mexican immigration prior to World War II was largely to rural southwestern areas where jobs in agriculture, mining and the railroads were found, more recent migrants have become increasingly urban although still concentrated in the southwest (Bean and Tienda, 1987).

Table 9 presents the geographic distribution of the Mexican-origin population from 1950 to 1990. By 1960 two states, California and Texas, contained the majority of the Mexican-origin population. However, the distribution of the Mexican-origin population within these states has changed significantly over time. For example, in 1960, Texas and California each contained around 31 percent of the Mexican-origin population. By 1990, California had 45 percent of this population while Texas had less than 30 percent. Given that the size of the Mexican-origin population was so similar in both states in 1960, the large increase in California suggests that it has become an increasingly attractive destination for migrants. In addition to a shifting a distribution of Mexican-origin individuals within the five southwestern states, there has been a decrease in the proportion of this population found only in these five states. In 1970, 87 percent of the Mexican-origin population lived in one of the five southwestern states. By 1990, 84 percent of this population did so. Other states such as Illinois, Michigan and Washington have attracted increasingly large Mexican-origin populations as well (Bean and Tienda, 1987). The decreasing geographic concentration of this group is likely to continue as the Mexican-origin population continues to grow in the next century.

Table 9
Mexican-origin Population in the Five Southwestern States: 1950 to 1990

Conclusion

While persons of Mexican ancestry have been part of the population of this country since its beginnings, they have become an increasingly large component of the population over the course of the twentieth century. This growth is a result of both natural increase and immigration from Mexico with legal migration contributing the most to the overall growth. The flow of migrants from Mexico to the United States has fluctuated with changes in the political and economic climates of both countries but has increased overall. The proportion of the Mexican-origin population in the United States made up of immigrants had been decreasing throughout the beginning of the century but has increased since 1960. Because the recent flow of immigrants from Mexico has been so large, the proportion of the Mexican-origin population that is foreign born will continue to be high and may, in fact, be larger than that of other ethnic groups in the United States.

The Mexican-origin population has and will continue to have an impact on the ethnic makeup of the United States. Not only will the proportion of the Mexican-origin population that is foreign born continue to be large but the Mexican-origin population in the United States will become an increasingly important component of the overall population, as the projections presented above indicate, probably becoming the largest minority group early in the next century. This growth has implications for the future social, economic and political conditions of the United States. Its young age structure relative to non-Hispanic whites, for example, means that the Mexican-origin population will contribute more to the working-age population, will have a greater stake in the educational system and may, as a result, become more politically active. In addition, since the Mexican-origin population in the United States will continue to be made up of many foreign-born individuals, both immigration policy in the United States and relations with Mexico will have an increasing impact on this portion of the U.S. population.

Note

1. According to the results from the Current Population Surveys (March, 1986 and 1996), the Mexican-origin population has increased from 62 percent of the Hispanic-origin population in 1986 to 63.4 percent in 1996.

QUANTIFICATION OF MIGRATION

Emigration: Implications for U.S. Immigration Policy Research

Ellen Percy Kraly

Introduction

Discussions of U.S. immigration trends and policy often rest on an implicit assumption that international migration to the United States is permanent. Research has revealed otherwise. Social demographic studies have shown that immigration has been related to significant levels of emigration of aliens and the foreign born throughout this century and continuing through the contemporary era. Between 1900 and 1980 approximately 30 million immigrants came to the United States, of which nearly 10 million returned or moved on to another country (Warren and Kraly 1985). The U.S. Bureau of the Census estimates that 195,000 foreign born residents emigrate from the United States each year. Moreover, the significance of emigration of immigrants appears to be characteristic of contemporary immigrant receiving nations. Among every 100 immigrants to Canada, 30 to 45 are estimated to eventually emigrate (Beaujot and Rappak 1986); of the settlers arriving in Australia since the second world war, perhaps one quarter have permanently departed (Lukomskyj and Richards 1986).

While emigration is increasingly identified by social scientists as an important analytic issue in the study of immigration, the implications of emigration for the formulation and implementation of U.S. immigration policy and programs remain

remarkably unarticulated. This paper considers emigration as an immigration policy issue for the United States. The general argument is that national immigration policy would be more effectively conceptualized, crafted and implemented with a better understanding of the dynamics of emigration among international migrants coming to the United States.

To be sure, our statistical image of immigration to the United States is shaped by a relatively small number of statutory and administrative concepts including admission of permanent resident aliens and nonimmigrants, refugee migration and asylum, and undocumented alien migration. Complementing trends in immigration with information about subsequent out-migration of aliens is likely to result in shifting conclusions about both the demography of immigration as well as the nature of social, economic and geographic effects. The statistical lens should be widened even further, moreover, to consider all sources of international migration to and from the United States including native born and naturalized U.S. citizens. Accordingly, a comprehensive appreciation of the dynamics of international migration will embed U.S. immigration trends, policy and issues within the broader context of international population movements emerging regionally and globally. Throughout the world international population movements are increasingly diverse embodying a widening range of geographic origins and destinations, reasons for migration, and social demographic characteristics (see Russell 1996; Martin 1994; Castles and Miller 1993). The emphasis on movements *to* rather than *from* the country blinds U.S. policy discussions to the connections between national policy issues and wider regional and global processes.

The paper seeks to adjust the lens of U.S. immigration policy analysis by considering issues concerning population movements out of the United States.
The analysis addresses four interrelated topics. First, I consider concepts of emigration and temporary international migration, raising issues in analysis and interpretation along the way. Second, I briefly and selectively review research on emigration for the United States. Third, I reflect upon the need for better information on emigration from United States for the design and implementation of U.S. immigration policy. Fourth, recommendations are offered concerning priorities for the collection of data and for research on international migration to and from the United States. Strategies for the study of emigration and temporary international migration encompass regional and bilateral perspectives on migration processes.

Two further comments concerning the approach taken here should be added. In several ways, this analysis builds upon a study prepared several years previously for the U.S. Immigration and Naturalization Service, Office of Plans and Analysis. That report, "Balancing the Equation: Federal Statistical Resources for the Measurement of Alien Emigration from the United States," represented an inventory and assessment of federal data relevant for the measurement of emigration

and offered recommendations for specific activities that might be pursued by the Immigration and Naturalization Service (INS) to this end. Several of the findings and recommendations of that study will be revisited for this analysis.

Second, discussions of the state of the art of emigration research often begin with calling attention to both the dearth of statistical information on the departures of immigrants from the United States and the consequent limitations of research and analysis on the subject. While this concern is well justified for the United States (hence, the current report!) it diverts our attention from what can be learned from methodologies underlying currently available estimates and from survey research concerning migration and immigrants, as well as from studies of emigration, return migration, and short-term migratory flows for other countries and regions of the world. Perhaps we in the United States have not taken sufficient advantage of perspectives on international migration and national policy concerns that have expressed in regions beyond the North American shores. Many countries in the developing world which have traditionally been regions of origin for international migrants now find themselves experiencing both return migration as well as other immigration and circular migration. These emerging trends are often understood as national and regional policy concerns regarding both migration as well as social and economic integration among countries. In her discussion of international migration data needs in Latin America, Maguid states,

> The changes which have occurred in the international migratory movements in Latin America and in the social, political and economic context in which they occur, both international and regional, stress the urgency of having adequate, reliable, up-to-date and continuous information for making or modifying migration policy (Maguid 1994, 39).

It is thus useful to consider approaches being pursued by other countries for generating information on international migration which is appropriate to process of national and regional policy formation.

Concepts of Emigration and Temporary International Migration

A variety of concepts concerning population movement from a country appear in the literature. Accordingly, emigration, return migration and circulation are special cases of international mobility (see Willekens 1994, 7-9; Gmelch 1980). Emigration is generally considered as the permanent migration from one country to another. The emigration of former international migrants includes return migration to the country of origin, and re-migration to a third country or region. For refugees,

return migration might considered repatriation. Obviously, nationals of a country can also emigrate, a process sometimes called expatriation.

Certainly the largest numbers of moves out of a country are of temporary duration in the form of travel for business or pleasure. Beyond travel and tourism, moreover, temporary or short-term departures for work or training are increasingly significant in population movements worldwide. The increasing diversity of forms of international mobility is reflected in the long list of concepts seeking to capture specific reasons for the moves: circulation, seasonal labor migration, border crossers or commuters travelling daily or weekly to work in a different country, travel for training and education, migration of professional transients. Each of these concepts implies moves into and out of countries. Critically, the concept of international circulation has been developed to refer to short-term labor mobility or migration that recurs at varying times and connects workers and perhaps their households to two or more places of work and residence (see Chapman and Prothero 1985; Conway 1988). Circulation may be considered an important dimension of economic and social integration between and among countries (see Bailey and Ellis 1993).

It is difficult to discuss these concepts without reference to specific national contexts, policies and statistical practices. To be sure, the challenge to specifying international migration concepts and terms reflects not so much demographic or sociological issues but more the constraints imposed by national migration control policies and statistical programs for measuring what are by definition bi- and multilateral processes. Progress toward standard concepts and definitions of international migration has involved international efforts throughout this century (see Kraly and Gnanasekaran 1987); implementation of international statistical concepts in national practices, however, has been uneven (see Simmons 1987; Kraly 1995).

Given our goal to connect emigration and circular migration patterns to U.S. immigration policy it is important to identify population groups whose departures are of interest. From a strictly demographic perspective, all residents of the United States are "at risk" of emigrating. For immigration policy analysis, it is the emigration of alien and foreign born residents of the country that is relevant. Alien residents include a diverse of group of people depending on how residence is conceived: aliens resident in the United States may be defined on the basis of legal status such as legal permanent resident alien; or the resident alien population may be considered as those non-U.S. citizens who fulfill residency rules of U.S. Census Bureau operations, such as permanent resident aliens, foreign students and undocumented migrants. By including naturalized U.S. citizens, the population of foreign born residents represents an even broader demographic concept of lifetime migrants to the United States and permits the analysis of relevant immigration policy issues. For example, cross-classification of the foreign born population by

citizenship status reveals the effect of naturalization on emigration behavior of former immigrants.

Most often, however, it is the available data source that dictates the boundaries of emigration analysis. Thus, census-based estimates of emigration refer to the foreign-born population and thus include both aliens and naturalized U.S. citizens enumerated in the decennial census. Bratsberg and Terrell's recent analysis of 'Americans living abroad' (1996) uses U.S. Department of State data on U.S. citizens registering with consular posts in foreign countries. The population abroad thus includes both native-born and naturalized U.S. citizens and as a result captures emigration, return migration and perhaps re-migration. Temporary migration and circulation are processes very difficult to study using official data sources and are more often considered in surveys and ethnographies investigating specific migrant streams and ethnic communities.

The emphasis here is on what is known and needed to be known about emigration and short-term and circular migration of international migrants to the United States. To best serve immigration policy analysis, moreover, the population of international migrants should be broadly conceptualized to capture existing and emerging trends in emigration and international mobility (see McNicoll 1992, 14). We should thus consider groups of aliens migrating to the United States both within and around U.S. immigration policies, specifically persons admitted for permanent resident status (including refugees), nonimmigrants who reside in the United States for significant periods of time such as students, workers and exchange visitors, and resident undocumented migrants. Patterns of emigration and circulation among the naturalized citizen population is also of interest given the connection of this group to policies governing immigrant and refugee admissions and settlement in the United States.

Research on Emigration from the United States

Suffice it to say that the emigration and temporary migration patterns of each of the groups just identified have not been fully covered in the research literature. Data for the study of emigration from the United States are limited. Federal statistical resources must be used creatively to produce estimates of emigration; surveys and field research on particular immigrant groups have provided information about short-term departures and patterns of circulation. Accordingly, this discussion of what is known about emigration begins with a summary discussion of U.S. data available for the study of emigration and population movements from the United States. I will then consider several studies of emigration and short-term mobility among immigrants with specific attention to recent estimates prepared by the Population Division of the U.S. Bureau of the Census. The review

by Karen Woodrow-Lafield (1997) provides a more comprehensive analysis of the state of the art of emigration studies for the United States and should be considered in tandem to this report.

U.S. Data on Emigration and Short-term Mobility

The need for federal data on emigration has been recognized for sometime (see Keely and Kraly 1979; Levine, Hill and Warren 1985; Warren and Kraly 1985). As a result, federal statistical resources concerning emigration have been documented and assessed in some detail (see for example, Kraly 1991; Woodrow-Lafield 1994, 1996b; Borjas and Bratsberg 1996). The first observation that is usually made concerning U.S. emigration data is that no comprehensive source of statistical information on emigration exists for the United States (see U.S. General Accounting Office 1998, 4). Data on the permanent departure of aliens and U.S. citizens were collected between 1908 and 1957 but the statistical program was discontinued because of uncertainty about the quality of the data. Since that time, alien emigration from the United States has been estimated using census data, administrative data sources collected by several federal agencies, and results of surveys and other field studies.

In 1991 I identified four federal agencies that collected data most relevant for the study of emigration among aliens and the foreign born population in the United States: U.S. Immigration and Naturalization Service (INS), U.S. Bureau of the Census, U.S. Social Security Administration and the U.S. Travel and Tourism Administration. Half a decade later the list remains essentially the same,[1] although some of these programs have been enhanced for purposes of emigration analysis. For example, while INS no longer collects data it defines as emigration data, the agency does in fact operate a program of statistical departure control for aliens with nonimmigrant visas. The Nonimmigrant Information System (NIIS) records the arrival and subsequent departure of nonimmigrants (excluding most Canadians and Mexicans entering for business or pleasure). The system is the basis for information on the legal entry of nonimmigrants and for the estimation of rates of visa overstay among groups of nonimmigrant aliens. The system has been used to measure length of stay among groups of nonimmigrants. Kraly and Warren (1991, 1992) used these data to estimate the number and characteristics of nonimmigrants who remained (hence resided) in the United States for more than one year and thus should be considered long-term immigrants according to United Nations standard definitions. The INS Statistics Division now publishes a regular report on nonimmigrant departures and patterns of length of stay among detailed visa categories.

Potentially, the NIIS program could be used to study international migration

and mobility behavior and correspondingly circulation patterns among selected groups of aliens by tracking the arrival-departure records of individuals over time. The volume of information processed in this information system is, of course, immense. INS has been encouraged in the past to consider sampling arrival-departure record as a strategy for promoting more detailed research on trends and characteristics of short-term international migration and mobility. Similarly, the existence of departure control for nonimmigrant aliens travelling by air raises the possibility or opportunity for collecting data (for statistical purposes) from permanent resident aliens departing the country as a means to study emigration and short-term mobility among immigrants.

During the past two decades, demographers at the U.S. Bureau of Census have made significant contributions to the study of emigration from the United States primarily through efforts to estimate intercensal levels of emigration among the foreign born. Warren and Peck's (1980) analysis of foreign born emigration for the 1960-70 decade laid the foundation for the use of residual techniques applied to international migration research. Warren and Passel (1987) produced estimates of emigration that were a by-product of their method to construct the legally resident alien population of the United States and ultimately the size of the undocumented population enumerated in the 1980 census. Ahmed and Robinson (1994), whose recent study will be discussed in some detail below, have used variations on this analytic theme to produce estimates of emigration among foreign born residents for the 1980-90 decade.

The Current Population Survey (CPS) has been explored as a basis for estimating emigration using a multiplicity research design. The Census Bureau initiated the collection of data on numbers and characteristics of relatives of U.S. residents living abroad in 1987 and continued data collection again in 1988 and 1989. Briefly, the approach relies on identifying for U.S. residents those 'consanquineal' immediate relatives (parents, siblings and children) who are nonresidents of the United States, and then determining whether any of these individuals are former U.S. residents and are living abroad temporarily or permanently (longer-term). The number of emigrants identified by this approach is biased by two broad sources of error. First, emigration is underestimated to the degree that emigrants did not leave relatives in the United States to report them; second, the number of emigrants will be overstated by the number of immediate relatives eligible to report the relative. According, the survey must weight the emigrant according to the probability of his or her relative being in the sample, i.e., the "multiplicity" associated with the emigration (see Woodrow 1996; Zaba 1987).

Two federal programs that continue to hold potential for the study of emigration are the U.S. Social Security Administration (SSA) and the U.S. Travel and Tourism Administration (USTTA). Each of these programs are considered in relative detail

in the 1991 report and will only briefly discussed here. SSA collects direct, if not comprehensive, data on the emigration of former U.S. immigrants as a by-product of its records on earnings and benefits. For example, records on social security beneficiaries residing abroad are maintained by SSA from which the number and some characteristics of persons who had previously lived in the United States (both foreign and native born) can be gleaned (see Kraly 1982).

The Continuous Work History Sample is a second social security data file with a capacity to generate information on emigration. This microdata file is maintained for research purposes, although with strict constraints on public and federal access, and permits the longitudinal analysis of changes in employment, earnings, benefits, disability, and geographic location of employment. Country of birth is also included in the data record. It may be feasible to estimate emigration among foreign born workers given information about changes in earnings and benefits claims. Finally, the USTTA has conducted air passenger surveys since 1983 for purposes of monitoring trends in international tourism and markets. The survey might be explored as an instrument for collecting data from different groups of aliens on intentions about reasons for departure and length of stay abroad.

Selected Studies of Emigration from the United States

Research on emigration from the United States is indeed limited, largely because of data sources. We can look to studies of historical patterns of emigration from the United States (for example, Axelrod 1972; Piore 1979; Warren and Kraly 1985) which have relied on historical emigration statistics to trace patterns of emigration, presumably return migration, among groups of immigrants to the United States. Contemporary studies of emigration of U.S. immigrants have relied in large part on census and administrative data sources to estimate levels and characteristics of emigration. For example, Jasso and Rosenzweig (1982) matched individual data records for immigrant admissions, naturalizations, and responses to the Alien Address Report Program (which ceased operating in 1981) to yield estimates of the proportion of the 1971 cohort of permanent resident aliens who had emigrated by 1979.

Recent research by Borjas and Bratsberg has combined several administrative and research data sources to estimate out-migration rates for the foreign born population resident in the United States in 1980. Also using a residual estimation approach Borjas and Bratsberg compare the enumerated foreign population with a constructed estimate of the foreign population for 1980. In developing this expected population, Borjas and Bratsberg wrestle with differences among statistical concepts of U.S. international migration. For example, they must adjust the census data on the foreign born for those international migrants which fulfill census residency

rules but are not included in INS data on 'immigrant',' that is, permanent resident alien, admissions. These groups include undocumented resident migrants enumerated in the census, and nonimmigrants such as many foreign students, temporary workers and trainees, exchange visitors, etc. who have a *de facto* residence in the country. In adjusting for these differences in data sources, the authors explore in the process the sensitivity of estimates to alternative assumptions. Research findings reveal out-migration rates which average 22 percent for the 1970-74 international migrant cohort and 18 percent for the 1975-79 cohort. These out-migration rates vary widely by region and country of origin. The out-migration rate for the 1975-80 cohort of immigrants from Mexico is nearly double the overall level, 42 percent, and for the Canadian cohort is much lower, 11 percent. The estimated rates provide a basis to test models of the determinants of out-migration rates among legal international migrants and patterns of selection of out-migrants among original immigrant cohorts (Borjas and Bratsberg 1994).

Estimates of emigration have also been derived from survey research. As described above, data on relatives living abroad of U.S. residents have been collected in several rounds of the Current Population Survey (CPS). Karen Woodrow-Lafield (1990, 1994) has analyzed these data to estimate numbers of surviving emigrants under a range of assumptions about emigrants without immediate relatives in the United States. Her findings have implications for both evidence about emigration levels as well as analytic issues in predicting future trends:

> The implied level of emigration in the 1980s appears similar to previous levels based on intercensal research for 1960-1970 and analyses of legally registered alien populations for 1965-80. ...Overall emigration levels are likely to be influenced by changing heterogeneity of the foreign-born population on country of origin, familial ties in the United States, and reasons for leaving their native country. Characteristic of legal immigrant cohorts since 1965 are increasing proportions from Latin American and Asia, from family preference categories and exempt family reunification provisions, and from refugee status. All of these characteristics would probably be associated with lower probability of return in the short-run (1994, 27-28).

The use of multiplicity techniques for the estimation of emigration holds clear potential for adding to our understanding of both levels of emigration as well as relationships between international migration and family structure of foreign born and native born persons in the United States. The approach thus deserves further consideration within the context of federal statistical resources.

Census-based estimates of emigration among the foreign-born population provide important information of levels and characteristics of emigrations for recent decades. As mentioned above, the first effort to estimate emigration for an intercensal

period was that of Warren and Peck (1980). Demographers at the U.S. Census Bureau, Population Division have continued to develop estimates of emigration among the foreign-born using residual estimation techniques most recently represented in the work of Bashir Ahmed and Gregory Robinson (1994). It is useful to consider closely the contribution of this analysis to research on emigration for at least three reasons. First, the study provides measures of foreign born emigration for the most current intercensal decade, 1980-90. Second, given the striking absence of empirically situated, comprehensive studies of emigration, the Ahmed-Robinson estimates emerge as a significant contribution to both scientific and policy discussions of the implications of U.S. emigration. Third, Ahmed and Robinson emphasize the importance of modelling emigration in the form of emigration rates rather than aggregate levels, and implicitly urge an appropriate break with the Census Bureau tradition of modelling international migration.

Because of noteworthy contributions of the Ahmed-Robinson research, as well as the prominence being given these estimates in current discussions, it is important to appreciate several important analytic issues that should be considered in interpreting the results of the analysis. An exploration of both the study's strengths and limitations will contribute to strengthening the argument for continued research on emigration from the United States.

Ahmed and Robinson use a combination of approaches to produce detailed estimates of emigration among the foreign born for the 1980-90 decade. A brief summary of their data and methodology is warranted. Data collected in the 1980 and 1990 decennial censuses is basis for estimation. This contrasts to complementary census-based research on international migration which combines census data with INS data on the admission of aliens who would likely be enumerated in the census, i.e,. permanent resident aliens, refugees, students, etc. (cf. Warren and Peck 1980; Warren and Passel 1987; Borjas and Bratsberg 1994). The Ahmed-Robinson analysis proceeds in two stages. First, the authors estimate the level and characteristics of emigrants among the foreign born population enumerated in the 1980 census, that is, the 1980 foreign born stock. A residual technique is used to compute the proportions of the foreign born population, by age, sex, year of entry and country of birth, who emigrated between 1980 and 1990. Survival rates were derived from comparison of life tables for different races developed by the Census Bureau (Ahmed and Robinson 1994, 4-5).

The second stage of analysis is devoted to the estimation of emigration among foreign born international migrants who entered the United States during the 1980-90 decade and were enumerated in the 1990 census. Cohorts of these international migrations are identified using the census question on year of entry. The rates of emigration computed for the 1980 foreign born population for migration cohorts prior to 1980 are applied to the 1980-90 international migration cohorts

to produce estimates of levels of emigration and a profile of the composition of emigration streams. The use of emigration rates results in a larger absolute annual level of emigration for the recent decade, 195,000, in comparison to the level of annual emigration assumed in national population estimates and projections (133,000). This higher level of emigration reflects the higher levels of immigration during the decade.

The Ahmed-Robinson analysis is an important contribution to what unfortunately is a relatively meager body of literature on overall levels and patterns of emigration from the United States. This research provides estimates of emigration for the recent stock and flow of lifetime international migrants and thus indicates the degree of permanence of settlement and length of stay among foreign born migrants to the United States. Second, these estimates seek to mine available U.S. census data to yield not only the level of emigration for the most recent intercensal decade but also characteristics of emigration streams among the foreign born. The paper provides geographic and social demographic detail for foreign born emigrants that is both provocative and relevant for the design of subsequent studies of emigration from the United States. Third, the results for both levels and patterns of emigration derive from the application of emigration rates applied to the foreign both stock in 1980 and international migrants arriving during the decade, disaggregated by age, sex, year of arrival and country of birth. The estimates are a function of a model or models of (e)migration behavior applied to shifting population composition. Thus, to a certain extent, the analysis shifts attention away from levels estimated by residual analysis to the study of migration propensity and behavior.

The limitations of the study are also addressed by the authors. Issues raised include assumptions about the level of population coverage in the successive censuses, choice of life tables, and analysis and interpretation of results for countries in which the estimation technique produced inconsistent levels of emigration. These issues in data and method should be considered somewhat more closely. Moreover, additional issues in theory and population modelling, and data quality and evaluation need to be critically entertained for an appropriate interpretation and use of the findings. I would suggest that five general analytic issues should be addressed in evaluating the Ahmed-Robinson estimates, all of which are interrelated: (1) the validity of their model of population change; (2) the assumptions about the relationship between types or categories of international migrants and migration behavior; (3) the relationship between model assumptions and migration theory and research; (4) issues concerning the quality and consistency of the data; and (5) the need for more extensive exploratory and sensitivity analysis.

Of these five areas of concern I believe the first, the appropriateness of the inherent model of population change for the foreign born population, is the most important for evaluating the merits of the Ahmed-Robinson estimates of emigration.

Estimation of levels and ultimately social demographic composition of emigration among recent international migrants (1980-90) derives from the application of rates of emigration computed for the foreign population who immigrated between 1970 and 1979 and were resident in the United States for the 1980 census enumeration. In fact, rates of emigration for the 1980-90 cohort of international migrants are not computed in this analysis, but current levels are computed on the basis of migration behaviors from the 1970-80 decade, converted to annual emigration rates and weighted by average length of stay estimated for the 1980-89 migrants.

Fundamentally, this model represents a conceptualization of population dynamics for recent international migrants that embodies a continuation or maintenance of emigration behaviors of earlier international migrants. Because of the shifting mix of legal/administrative categories of international migrants these emigration rates may not be appropriate for the migrant cohorts of the 1980s (this issue will also be considered below). The analytic approach and ultimately the results deriving from this model of population change implies, it appears to me, that we have access to more information about emigration behavior than in fact we do. In short, there is no new information about emigration behavior, that is, age-sex-country specific rates of emigration, for the international migration cohorts of the 1980s. Ahmed and Robinson have estimated levels of recent emigration based on a persistence of emigration rates estimated for the immigrants who entered during the 1970s.

This line of argument can also be extended to the model's assumptions about the other components of population change. That is, one might contend with the choice of the survival rates applied to the racial groupings of the foreign born population as well as the essentially linear approach to estimating average age at migration and average length of stay among international migration cohorts.

A second general issue, mentioned briefly above, concerns assumptions in the analysis and discussion about the relationship between types or categories of international migrants and migration behavior. Within the discussion, the authors recognize changing composition of international migration with regard to legal and administrative categories such as permanent resident aliens, refugees, students, and undocumented migrants (Ahmed and Robinson 1994, 10-11). They also suggest in reasonable fashion that different categories of aliens coming to the United States are likely to have different propensities to emigrate, either by returning to the country of origin or emigrating to another country. The basis for assumptions about rates of emigration for 'nonselected' countries, for example, relies in large part on hypotheses concerning the likely emigration behavior of aliens legalized under IRCA and refugees. In spite of this line of reasoning, however, the analysis does not model or incorporate alternative or diverse emigration behaviors but, as emphasized above, adopts a model of migration that derives

from an earlier decade and from what is certainly a different mix of categories even within country of birth. There is thus a missed opportunity in the paper's discussion to underscore the need for basic research on patterns of return migration, re-migration, and international mobility and circulation among various legal and administrative categories of international migrants to the United States as well as among nationalities.

A third area of concern is the relationship between model assumptions and existing migration theory and research. Again, this issue in connected to the previous concerns about the underlying population model and the relationship between immigration categories and migration behaviors. Several components of the model assume static conditions. For example, it is assumed that persons admitted as refugees are less likely to return to their country of origin. A more dynamic perspective on refugee migration and international migration generally might at least entertain the possibility that conditions in both the sending and receiving countries may change; thus migration behaviors may vary not only over the life course and by length of stay but also in relation to the context of migration. Similarly, the model assumes proportional levels of census coverage error that do not change for migrant populations between 1980 and 1990. One might predict on the basis of the sociology of immigrant settlement, however, that rates of population coverage would be greater at the second census date rather than the earlier date, not necessarily because of differences in census administration but because of greater knowledge among earlier, more settled immigrant populations about civic participation and the U.S. government in comparison to more recent immigrants. Moreover, the basis for establishing the assumed level of emigration among "unselected countries" should be better grounded in theory and research on international migration pertaining to the countries concerned. This is particularly necessary given that the basic model of population change implies levels of emigration very much at odds with the assumption that emigration rates for these countries are "50 percent of the rates for selected countries" (Ahmed and Robinson 1994, 11).

A fourth set of issues concerns the quality and consistency of census data. The Ahmed-Robinson estimates derive from both explicit and implicit assumptions about the validity of several key census items. Evaluation of data on age and nativity among the foreign born is necessary. Moreover, recent research by Ellis and Wright (1996) cast doubt on the quality of data on length of stay in the United States by estimating that perhaps one third of the foreign born population who indicated they 'came to stay in' the United States between 1985 and 1990 had actually entered before 1985. The heavy reliance on both year of entry and age to measure average age at entry further necessitates the critical evaluation of these census items. Finally and relatedly, there is a need in the analysis for more extensive exploratory and sensitivity analysis. As mentioned above, the results of varying assumptions about

changes in census coverage among immigrant populations should be presented. Similarly, the sensitivity of emigration estimates to varying assumptions about emigration rates for nonselected countries should be explored. In general, the analysis does not lead one to be fully confident that the implications of either model assumptions or data quality have been fully examined.

Both the strengths and limitations of the Ahmed and Robinson study serve to fuel the argument for increased research on emigration. The findings point to the demographic significant of emigration. The lack of adequate data to model the propensity among former immigrants to emigrate for recent years reveals the weaknesses of the federal systems of international migration statistics.

These selected studies which have sought to develop comprehensive estimates of levels of emigration from the United States often interpret their findings in relationship to dimensions of return migration of international migrants, in spite of the fact that no information is available on the destination of the out-migrants, reasons for departure, or intentions about permanence or length of stay of the move. Moreover, given the estimation methodology and data sources, these approaches are not able to address either length of absence or short-term moves out of the United States among groups of international migrants. Referring to the situation of Canada, Beaujot and Rappak (nd) reflect on the problems in interpreting the results of emigration studies which apply residual estimation techniques to a combination of administrative data sources:

> This discussion of definitions, data and methods makes it clear that immigration and emigration are somewhat "fluid" terms whose statistical capture is far from simple. For instance, some "landed immigrants" (permanent, by definition) may have a very limited stay in Canada while other temporary workers may eventually stay for a long time. Some persons are defined as emigrants just because they happened to be resident abroad on a census day, while other leave for long periods between censuses and come back without being noticed (Beaujot and Rappak nd, 26).

These issues are equally pertinent to the interpretation of emigration estimates for the U.S. foreign born population.

As mentioned above, among official data sources, the Nonimmigrant Information System (NIIS) holds some potential for the analysis of international mobility, short-term migration, and circular migration among legal aliens in the United States, specifically among nonimmigrants. Kraly and Warren (1991, 1992) have used these data for identifying those (departing) nonimmigrants whose length of stay was greater than one year. The information system could also be used to monitor temporal and geographic patterns of international mobility among categories of nonimmigrants and by the few social demographic characteristics

available on the arrival-departure record (I-94 form). Moreover, the administration of arrival-departure control might be modified ('for statistical purposes') to document the international mobility of permanent resident aliens. In Australia, Lukomskyj and Richards (1986) used this approach to study emigration among 'visaed settlers' who immigrated in 1980. Their analysis of records in the Movement Data Base permitted not only the measurement of rate of out-migration (about 9 percent) among this immigrant cohort, but also of the characteristics of emigrants relative to immigrants.

Not captured in the Nonimmigrant Information System is the vast majority of moves of aliens across the Mexican and Canadian borders of the United States. For the most part, information on short-term international mobility and circular migration among U.S. international migrants has been generated through survey and field studies of specific migrant streams and communities. The list of relevant scholarship is broad and draws from a long history in social science. Certainly the ethnosurvey research conducted by Massey and his colleagues (see Massey, et al., 1987) has been central in both revealing the dynamics and circularity of migration of Mexicans between communities in Mexico and the United States as well as demonstrating the value of longitudinal survey and ethnographic research for the study of international migration. The Philippines Migration Study similarly reveals the relevance of surveys to reveal international mobility processes among specific migrant streams (Fawcett and Arnold 1987). Research by Weiser (1988) and Bailey and Ellis (1993) on return migration among Puerto Rican women illustrates the use of specialized surveys, in this case, the Puerto Rican Fertility and Family Planning Assessment, to yield insight into the behavioral dynamics of circular migration.

Fawcett and Arnold make the most eloquent case for the use of surveys for the study of international migration processes and emphasizing conceptual issues highlighted earlier:

> "International migration" is not a unitary concept; rather, it is a broad category encompassing population movements that differ in their timing, frequency, purposes, and locational boundaries. Substantive and theoretical issues are greatly influenced by how spatial mobility is conceptualized and measured. The advantage of surveys in this respect is mainly in the amount of information collected. A migration history can show frequency of moves, information about dates and places can be obtained for long-term and short-term movements, and reasons for moves and other motivational data can be collected. With such data in hand, the researcher can devise different typologies and measures of movement, thus ensuring that the key dependent or independent variable is measured in a way that is congruent with the conceptual posture of the study (1529).

The Need for Information on Emigration from the United States

An early report of the U.S. General Accounting Office succinctly states the policy rationale for the study of emigration of international migrants coming to the United States: "[e]migration is a factor that underlies all immigrant impacts because the magnitude of those impacts depends upon the length of time that immigrants reside in the United States" (GAO 1989, 47; see also GAO 1988). Moreover, the size and composition of the international migrant populations resident population which generates policy relevant impacts reflect the dynamics of change in those populations.

For many countries, the argument that emigration and return migration is a significant dimension of international migration policy analysis has already been made. In Canada, the MacDonald Commission urged the consideration of the long-term impacts of immigration on population change and economic growth (Beaujot and Rappak nd, 3; see also Michalowski 1991). In Australia, official reports have acknowledged the significance of return migration following the admission of permanent settlers (Lukomskyj and Richard 1986, 603). The need for continuous and reliable information on mobility and migration among countries in Latin America has been considered in discussions of national migration policies and also economic integration within the region (see Maquid 1993).

There is a statutory rationale for considering emigration in light of U.S. immigration policy concerns. The Triennial Report to Congress mandated by the 1986 Immigration Reform and Control Act is to include an assessment of the impacts of immigration on U.S. society, economic and population. Furthermore, the 1990 amendments to the Immigration and Nationality Act require that the "social, demographic and natural resources impact of immigration..." be determined (see Sec.141(c)(1)(C)). To restate the obvious, the 'impacts' of immigration can only be examined with evidence about the international migrant populations in the United States and how those populations are changing in size, characteristics and behaviors.

But the argument for better data on emigration and international mobility must derive from more fundamental principles of public policy analysis than solely the reporting requirements of the current law. If U.S. immigration policy is to serve national and international interests, the policy should undergo ongoing critical analysis informed by knowledge about patterns of change in causes, consequences and characteristics of international migration to the United States. From this premise, at least four general arguments can be offered for the necessity of improving national statistical resources for the study of emigration and the international mobility of U.S. immigrants. These include the benefits of information on U.S. population dynamics, economic and human resource issues, social demographic accounting

and the planning process, and issues of social and economic integration of the United States with other countries and regions of the world.

Interpreting National Population Dynamics and Regional Change

U.S. immigration policy does not exist to serve demographic ends. Concern about the volume of immigration to the United States, however, is reflected in annual ceilings, 'pierceable' or not, that are constructed to limit annual levels of immigration for permanent residence. It is important that the image of immigration trends is connected to real migration processes. The reality is that while many immigrants come to the United States intending to remain and do so permanently, some aliens with permanent resident visas emigrate permanently and others depart the country for temporary periods of time. Demographic research for the United States, as well as other immigrant receiving countries, suggests that proportions of immigrants emigrating are range upwards to 30 percent if not higher. Similarly, aliens arriving on nonimmigrant visas may remain in the country permanently by adjusting to permanent resident status. Kraly and Warren (1991) have shown that perhaps 100,000 nonimmigrants will depart after lengthy stays; many of these are likely to move into and out of the country on a recurring basis.

Policy makers and program managers are most certainly interested in the numbers, characteristics, and needs of international migrants, particularly permanent resident aliens and undocumented migrants, in their constituencies and communities of operation at any point in time as well as changes over time. The picture of international migrant populations painted through admissions and arrivals data is incomplete without corresponding information on departures; the snapshots of immigrant communities from census data are miss the dynamics of change in the national population and local communities. Thus, if the public and policy makers are to appreciate the relationship between international migration trends and immigration policy proposals, the evidence must be complete. When an annual level of immigration is reported, for example, "...in 1994, 804,416 immigrants were admitted to the United States... (U.S. Department of Justice 1996)" we should all be enlightened enough to implicitly add, "...of which about one quarter or one third are likely to emigrate...."

Without comprehensive data on emigration among groups of international migrants, we are not able to effectively understand current demographic change or project population growth in the near future. The lack of complete information on components of population change is particularly problematic for analysis of the impacts of international migration below the national level—for regions, states, metropolitan areas, and local communities in the United States (see Greenwood and Ragland

1991; Kraly 1995, 52-53) where migration is usually the most significant component of population change. Furthermore, demographic analyses, for example, those taking the form of population models and projections, require information on emigration in order to construct realistic trends international migration under alternative policy scenarios. (Kraly 1995, 1997; see also Michalowksi 1991).

Economic Consequences of Immigration and Human Resource Issues

Debates about U.S. immigration continue to address issues concerning the economic implications of immigration levels and composition. Changes in the structure of the visa preference system introduced in the 1990 amendments underscored the heightened interest in Congress considering immigration as a route to enhance job creation and economic growth. Increasingly, there is public concern about the implications of U.S. immigration for social policy and entitlement programs. To some observers, the Immigration Control and Financial Responsibility Act of 1996 represented a move to restrict legal immigration through reduced access to public programs including health services, welfare programs and public education.

Information about return and re-migration of U.S. immigrants is fundamental to the analysis of issues concerning immigration and economic growth in the United States, labor force growth, and human resource needs. Oded Stark states that determining why and which international migrants return to countries of origin is the "frontier of international migration research." If the skill composition of migration flows can be shown to be responsive to concrete policies, real-world concerns are well served by the provision of clear answers to these questions. And real world-concerns, in this context, are real indeed because the numbers of those who return are, generally speaking, anything but trivial (Stark 1995: 55-56). Again, in the case of both Canada and Australia there has been policy research devoted to the implications of return migration for the stock of landed immigrants and for the loss on returns to investment in the settlement and adjustment process of immigrants. Lukomskyj and Richards comment on the significance of return migration for Australia because both

> ...the loss of skills and capital... and settler arrivals represent an initial cost to Australia in terms of operating the migration programs and providing post-arrival services and assistance. There is less return for the initial 'investment' in those migrants who later depart... (1986, 604).

Borjas has consistently raised the issue of emigration in relationship the analysis of the economic impacts of U.S. immigration and the skills and education levels of immigrant workers (see Borjas 1987, 1990). Recent research by Borjas and Bratsberg

(1994, 1996) considers how the human capital characteristics of groups of immigrants are related to the process of return migration and concludes that

> ...return migration intensifies the type of selection that generated the immigrant flow in the first place... if the immigrant flow is positively selected, so that immigrants have above average skills, the return migrants will be the least skilled immigrants... if the immigrant flow is negatively selected, the return migrants will be the most skilled immigrants (1994, 25).

Information on migration intentions among immigrants, such those data collected in the Legalized Alien Population Surveys may enhance the study of emigration decision-making and emigrant selectivity (see Woodrow-Lafield 1996; cf. Dustmann 1994).

Demographic Accounting and Public Policy and Planning

As implied above, if national statistical accounts are to serve the process of planning and analysis of public policy then the statistical systems must be able both capture reality as well as anticipate emerging trends and phenomena. Philip Martin emphasizes the importance for national migration policies of appreciating the basic "facts" of international migration (Martin 1994, 102). National statistical systems should facilitate the production of those facts and thus should not embody only administrative or legal concepts deriving from policies and laws in currently in place, but should also be conceptually flexible to permit the gazing at trends through a different policy lens. Reflecting on patterns of migration between Australia and New Zealand McNicoll wryly observes, "[a] demographic accounting system is an arbitrary construct, usually chosen to overlay a distinct polity (14)."

U.S. international migration statistics are generated as products of the administration of laws and programs concerning the admission and status of aliens in the United States, hence the absence of emigration data. Furthermore, there is a fundamental mismatch between official statistical concepts, which tend to divide the international entry of aliens into three categories—permanent, temporary and illegal, and the recurring patterns of international migration and mobility experienced by large numbers of aliens entering the United States from Mexico and regions in the Caribbean, in particular (Massey 1987; National Heritage Institute 1995, 7). Improved information on current and evolving patterns of emigration and international mobility would serve not only to evaluate current U.S. immigration policy but also to *anticipate* the need for shifts in policy and redesign of programs. Furthermore, flexibility in measuring both immigration and emigration within statistical systems would enhance the capacity of demographic accounts to contribute

to the broad enterprise of international migration policy analysis (Zlotnik 1987; Fawcett and Arnold 1987).

Immigration Policy, International Relations and Regional Integration

Morokvasic and De Tinguy have observed that since 1989 Central Europe has experienced new forms of inter- and intra-regional population movements and note that "[p]eople seem to go West in order to eventually remain in the East—where they reside" (1993, 261). International population movements throughout the world are embedded in widening economic and demographic regional differences as well as in increasingly extensive social and economic linkages between and among countries and communities (Russell 1996; Martin 1994). Efforts to control or manage international migration to the United States will depend in large part on the recognition of the place of the United States in the global and regional economy and the significance of social relations in shrinking the distance between sending and receiving communities across seemingly wide geographic space (see Papademetriou 1984, 267). Comprehensive study of current and emerging migration patterns is critically needed for analysis of regional economic integration of Mexico and the United States, as well as for the United States and other regions in Latin America and the Caribbean.

These ideas are not new and have been articulated clearly through the research program of the U.S. Commission for the Study of International Migration and Cooperative Economic Development (see also Teitelbaum and Weiner 1995). Emigration, particularly circulation, moreover, is a critical dimension of the interdependence between and among countries. The study of emigration and international mobility among international migrants to the United States provides evidence about trends in international relations and connections and the flows of human and perhaps other forms of capital and investment, and thus can enhance national understanding of the role of the United States in global change. This statement is dramatic and presumptuous. Given the entrenched view that alien immigration to the United States is permanent, however, some provocation would seem warranted.

Priorities for Emigration Research for the United States

The general conclusions of the previous (1991) report on emigration data noted first, no comprehensive, ongoing source of statistical information on emigration exists for the United States; second, in the near term, the analysis of emigration

among U.S. immigrants would rely heavily on estimates of migration patterns among the foreign born population and selected groups of aliens; and third, federal statistical resources that have the potential for the measurement of emigration are relatively inaccessible for research by analysts both in and outside the government (Kraly 1991, 25-26). These conclusions remain essentially intact.

Several of the report's specific recommendations to INS concerning emigration research, however, have been implemented. For example, INS has taken an active role in the launching of a longitudinal survey of immigrants in the United States which should yield indirect evidence about emigration among permanent resident aliens. Analysis of data on length of stay among departing nonimmigrants has been continued. There have been interagency discussions concerning the analysis of administrative data sets, both SSA files and the USTTA air passenger survey, for purposes of studying emigration and other dimensions of international migration to and from the United States.

It will be important to continue build upon these initiatives. Specifically, three broad research strategies concerning emigration and international mobility of U.S. immigrants should be given priority in order to support national immigration policy analysis. First, coordination and collaboration should be encouraged among policy analysts and statisticians within those federal agencies which participate in immigration policy analysis. Continued exploration of administrative data files for the analysis and estimation of emigration and international mobility should be pursued. For example, the mission and scope of the Nonimmigrant Information System should be expanded to include the study of international movements of both nonimmigrant and permanent resident aliens. Analysts at INS and the Census Bureau's Population Division should continue to work together to estimate emigration of the foreign born using residual estimation techniques and to take more complete advantage of emigration data (generated through multiplicity survey design) and information on the foreign born population collected in previous and future Curre¡nt Population Surveys. Further consideration of SSA data for the study of both emigration and immigration should occur. It will be useful, moreover, for federal analysts to consider strategies for generating data on emigration and international mobility used by statistical offices of other countries notably Canada and Australia, throughout Europe (see Willekens 1994), and Latin America (Maguid 1993).

Second, survey approaches to studying emigration, return and re-migration as well as circular migration among international migrants should be pursued. Particularly critical is collaboration among agencies to revisit the use of multiplicity research design in the Current Population Survey to generate direct estimates of emigration and length of stay among immigrants to the United States. Support for longitudinal survey research on U.S. immigrants, such as the New Immigrant Survey currently underway, should continue. Analysis of the results of

the Legalized Alien Population Surveys should be supported for purposes of emigration research (see Woodrow-Lafield 1996). Again, the use of surveys by other countries, for example, the Air Passenger Survey used in the United Kingdom and the German Socioeconomic Panel Survey (Dustmann 1994), and the range of strategies pursued in many developing countries (see, for example, Altaf 1992; Apraku 1991; ESCWA Secretariat 1993) should provide valuable perspective on the use of survey research for the estimation of emigration and international mobility using both direct and indirect techniques (see Zaba 1987; Larsen and Sullivan 1987). Particular attention should be given to the development of sampling methodology for surveys of alien departures from the United States at both air and land border ports.

Third, the policy importance of information on emigration and international mobility should be reflected in greater use of ethnosurveys for the longitudinal study of specific immigrant streams between communities within countries of origin and the United States. A record of scholarship exists demonstrating the value of combining sample survey methodology with ethnographic approaches for generating comprehensive information on the dynamics of international migration and mobility for particular migration communities and locales in the United States. Commitment to longitudinal research programs of this type would serve to provide data tapping emerging patterns and forms of international population movement in diverse regional contexts.

These three areas of research activity do not represent remarkably new ideas for research on emigration and mobility among U.S. immigrants. At present, most researchers interested in U.S. immigration and emigration have relatively clear visions of both what might feasibly be accomplished within the current structure of the federal statistical system, as well as what new research initiatives would be most useful for increasing our reservoir of information about out-migration of U.S. immigrants. What might be added to these visions, however, is attention to process. The endeavor of U.S. immigration policy analysis would benefit from a structure of human and statistical resources that results in focussed and coordinated attention to issues concerning international migration as a dynamic process to and from the United States. In an important paper, Frans Willekens (1994) considers both approaches to "...bridging the gap between available data on international migration flows and the information for policy making and research" (1994,1) in Europe. While the construction of a coordinated data base among European countries is emphasized, Willekens also notes the importance of 'expert judgement' in shaping migration models and in interpreting results. This perspective is usefully considered for the United States in the form a consortium of researchers focussing specifically on issues of emigration, international mobility among groups of international migrants to the United States.

It may be worthwhile to ponder the creation of a "Program of Research on Immigration, Emigration and Circulation among International Migrants to the United States." Such a program could provide a structure for coordinated efforts to measure, estimate and monitor emigration and international mobility. Through meetings and publications, an ongoing mechanism could be established for encouraging collaboration and exchange between and among analysts in the United States as well as with researchers conducting relevant work in other countries. Such an organizational framework would also have symbolic significance as formal recognition that international migration both to and from the United States is a dynamic and complex process which should be appropriately reflected in U.S. immigration policy.

Note

1. The U.S. Department of State, Bureau of Consular Affairs, U.S. Internal Revenue Service and the U.S. Department of Defense were also identified as potential sources of statistical information on U.S. residents living abroad. While the scope and accessibility for research of these statistical programs limits their usefulness for the study of alien emigration, it may be useful to reconsider these programs for purposes of migration modelling and estimation.

Quantification of Migration

Estimating Authorized Immigration

Karen A. Woodrow-Lafield

Introduction

The linguistic tools of the demographer studying international migration describe discrete events as biological events of birth and death. This is not so because someone who has migrated may easily return to the place of origin, negating the migration event. Migration demographers must incorporate the complexities of place and time. With a heightened awareness of the fluidity of population movements, especially those across the southern border, there has also emerged an awareness of the confluence of international population factors, world systems, social networks, and modern technology for creating a continuum of transnational migration.

The initial Immigration and Nationality Act of 1952 retained several provisions from earlier legislation and introduced important changes, continuing the use of quotas (based on the 1920 population), restricting Eastern Hemisphere to about 150,000 immigrants without any restriction on the Western Hemisphere, and establishing a preference system based on family relationships and labor skills. Subsequently, in 1965, the Immigration and Nationality Act Amendments discontinued the use of quotas, changed the limit and distribution for immigration visas for the Eastern Hemisphere, and established an annual ceiling of 120,000

for the Western Hemisphere, otherwise without restriction. Per-country limits were made applicable to the Western Hemisphere in 1976 and, two years later, a combined ceiling of 290,000 with a single seven-category preference system was established for both hemispheres. (See Levine, Hill, and Warren 1985 or U.S. Immigration and Naturalization Service 1991.) This preference system remains in effect with incremental changes over the decades and greater changes implemented through the Immigration Act of 1990 (IA90). Considering recent levels, Congress established a piercable cap on legal immigration. Apart from authorized immigration, social scientists do not enthusiastically agree upon a feasible role of policy in controlling illegal immigration (Cornelius, Martin, and Hollifield 1994; Massey 1996).

This study takes the following course. First, a conceptual framework for analyzing migration by legal status is set forth, followed by an operational framework with review of data on legal migration, statistical data systems, and official statistics. The next section explicates the discontinuities in measuring legal migration to the United States. These gaps derive in part from the fragmentation of statistical functions within the federal government. After explicitly referring to the criteria for measuring legal migration, prior estimates of legal migration are reviewed and discussed as to methodological strength. At that point, an assessment of legal migration from all countries and from Mexico is made based on existing data, alternative assumptions, and carefully explained logic. Two major concerns about establishing consensus about unauthorized or undocumented migration levels are accuracy in demographic accounting for the legally resident foreign-born and Mexico-born populations and completeness, both absolutely and relative to the legally resident populations, of total foreign-born and Mexican-born population statistics for the United States. I have addressed the latter elsewhere (Woodrow-Lafield 1991a, 1995a, Robinson et al. 1993). Finally, I address research priorities for the U.S. and Mexican governments on the measurement of migration between the two countries by legal status.

Conceptual Framework

For a substantial portion of the history of immigration in U.S. immigration statistics reported since 1820, all migration was legal because there was no legislation to prohibit entry of aliens until 1875 (Act of March 3, 1875, 18 Stat. 477). At that time, the policy of direct federal regulation of immigration was established with prohibitions for the first time on entry of undesirable migrants. The responsibility of reporting immigration statistics was given to the Bureau of Immigration of the U.S. Department of Labor in 1892, the forerunner of the U.S. Immigration and Naturalization Service (INS). Throughout the 20th century, apprehensions of illegal

aliens have illustrated that migration to the United States consists of unauthorized or undocumented as well as legal migrants.

For population and immigration policy making, certain other criteria emerge as relevant, such as social capital, nature of consanguineal or affinal ties with legally resident individuals, especially U.S. citizens, and human capital, as influencing opportunities to immigrate legally on the basis of skills. At first glance, these might seem exogenous to an effort to quantify contemporary authorized immigration, but these criteria should be considered as endogenous. Migration between Mexico and the United States is multi-dimensional, to say the least, and always has been very complex.

The indexing criteria for conceptualizing migration are historical time, place, intention, legal status, and duration. Historical time must be specified as a referent with remaining criteria. Place criteria refer to geographical location with reference to national boundaries. These are usually well established, especially for the United States, but there may be international disputes about boundaries or fluctuations over time. When an individual has changed places with respect to crossing from the nation of origin into another, then a migration event has occurred in historical time.

Two further criteria, intention with respect to length of stay and actual duration or length of stay, based on historical time based measures, characterize the migration event as to whether long-term or short-term. Intentions may or may not correspond with actual behavior, that is, there may be inconsistencies as individuals' actual behavior deviates from intentions of long-term or short-term migration. The differences between temporary and permanent migrations can appear at the time of initial entry into the United States or may evolve during a migrant's period of presence. A migrant has intentions to either stay temporarily or settle for long durations or a lifetime. Among those who intend to permanently migrate, some will reverse their intentions and return migrate, re-migrate, emigrate or initiate a series of intermittent residences. Among those who intend to be in the United States for a few months or up to one year, this intention may evolve into an intention to stay permanently. There will be varying intensities and successes of activities to seek opportunities for settling in the United States.

Type of legal status at entry into the United States can signal whether the migration is temporary or permanent, but the event may ultimately prove to be the reverse of its initial appearance because the underlying intentions may differ from the outset or may change. The presumption is that those entering with lawful permanent residence are likely to live here unless they choose to emigrate, but there is anecdotal evidence of dual residence lifestyles. Similarly, the general presumption is that those entering with permission to stay for limited duration are not lifetime migrants. If such a movement conforms to the legal structure in the

new nation of residence, then the migration is authorized. Those entitled to remain for their lifetimes are known as immigrants, or lawful permanent residents. Otherwise, the migration would be described as illegal, undocumented, or unauthorized. In addition, some authorized migrations are subject to temporal constraints in that the legality of admission is conditional and may expire or be revoked. Some individuals who entered legally may thus become unauthorized or undocumented or of uncertain status. The reverse may also happen; i.e., some that entered illegally may subsequently acquire legal status. Historical time and duration are thus critical referents in regard to legal status.

Combining these indexing criteria, a set of mutually exclusive categories is obtained for application to the migration events, into the United States as of a specific date. These are:

- Lawfully permanent resident from date of arrival;
- Lawful entrant who remained in a temporarily lawful status for a short-term stay;
- Lawful entrant who remained in a temporarily lawful status for a long-term stay;
- Lawful entrant who subsequently became undocumented or unauthorized for a short-term stay;
- Lawful entrant who subsequently became undocumented or unauthorized for a long-term stay;
- Lawful entrant who subsequently became lawfully permanent resident;
- Unauthorized or undocumented entrant who subsequently became temporarily lawful for a short-term stay;
- Unauthorized or undocumented entrant who subsequently became temporarily lawful for a long-term stay;
- Unauthorized or undocumented entrant who subsequently became lawfully permanent resident;
- Unauthorized or undocumented entrant who remained in that status.

The conceptual framework seeks to blend the dynamics of migration events with the demographics of population composition by legal status and inter-regional geography. The research problem merits adoption of multi-regional and multi-status modeling as devised for demographic behaviors of status transitions. Such models make rigorous data demands as to scope and detail, which are obviously improbable with respect to clandestine transitions.

Operational Framework

Time-reference

A corresponding analytical or operational framework seeks to translate these concepts to data realities. It is useful to consider the fundamental types of temporal treatment by which migration and, specifically, authorized migration might be studied.

Cross-Sectional or Historical

Cross-sectional studies generally use questions on place of birth, citizenship, and period of entry or immigration and measure net immigration as of the survey or census date. The decennial census in the United States is meant to encompass the *de facto* population, according to criteria of "usual residence." Migrants whose stays are so temporary as to consist of only days or weeks would not be enumerated if their stays occurred around the April 1 date. Self-identification "usual resident" would lead to inclusion of some migrants without permission to stay permanently, even ones of unauthorized or undocumented status.

Because there is not usually a question about migration or residence status in national surveys and the universe is the *de facto* population, the measure includes authorized and unauthorized or undocumented migrants and this practice has been upheld judicially (Passel and Woodrow 1984a).

Data for the more recent entrants are tainted with inclusion of temporary, especially unauthorized or undocumented, migrants so that cross-sectional data for earlier entrants are more representative of the settler population. Curiously, when there are both questions on period of entry and retrospective residence history, there can be a lack of correspondence (Ellis and Wright 1996). If there were a question about legal status, there might seem to be a higher incidence of unauthorized or undocumented status and temporary residence among more recent entrants than among earlier entrants.

Longitudinal

The simplest longitudinal approach, *longitudinal studies with cross-sectional data,* would present detail about the foreign-born population, or a subgroup such as unauthorized or authorized residents, at two or more dates. An example is demographic comparison of data for legally resident aliens in the United States according to an annual, administrative database to discern loss or departures (Levine, Hill, and Warren 1985; Warren and Passel 1987a, b; Jasso and Rosenzweig 1990). Another example, for more general migration, is comparison of the foreign-born

population in two or more censuses, that is, net immigration as of two or more dates, with indexing on period of entry or immigration so that an entry cohort may be followed over time. Such longitudinally-oriented analyses might endeavor to address demographic aspects of cohort change (Warren and Peck 1980) or cohort change as to earnings assimilation, public assistance utilization, residential overcrowding, and completion of naturalization (Borjas 1988; Myers and Lee 1996; Smith 1992; Jensen 1988; Woodrow-Lafield 1996d). Ideally, the indexing criteria would be sufficient to control for sources of heterogeneity, but dilution of the cohort through return migration is a source of unobserved or uncontrolled heterogeneity.

An ideal study is to follow migrants' experience over time to learn about their transitions among immigration statuses and their socioeconomic experiences. A pilot study is underway that follows immigrants and nonimmigrants over several years. An alternative is a retrospective orientation, such as gathering life histories within an ethnosurvey design such as for the Mexican Migration Project (Massey 1987). Building legal status histories is invasive, but these could be acquired more easily with ethnographic methods than with official government surveys.

Two approaches blend cross-sectional and longitudinal orientations. First, an example of *cross-sectional analyses of longitudinal data* is estimation of nonimmigrant overstays or nonimmigrants becoming unauthorized based on ongoing data collection of nonimmigrant arrival records and departure records (Warren 1986, 1990). Another example is presentation of net unauthorized or undocumented immigration based on apprehensions modeling derived from migration trip histories (Massey and Singer 1995). Each of these approaches could be extended to the incidence of authorized stays.

The units of analysis might involve individuals, families, households, family networks, or cohorts, e.g., birth years. The individual level of analysis is the most prevalent across substantive analyses, simply because it is most convenient for data collection, but migration is based in family networks (Boyd 1989). A single data collection effort can be flexible across multiple units of analysis, as the Legalized Population Surveys (LPS and LPS2) (U.S. Immigration and Naturalization Service 1992a; U.S. Department of Labor 1996) acquired individual-level data on legalized immigrants, current residence status for household members, and reported migration intentions for non-U.S. resident family members (Woodrow-Lafield 1994a, 1995b, 1996b). These studies showed that families and households of legalized immigrants are mixed as to residence status, including some unauthorized residents. In addition, U.S. born children appear as do lawful permanent residents and naturalized citizens.

One line of research on quantifying authorized migration seeks to cumulate subsequent immigration within a family network with respect to the initial legal immigrant, that is, the goal is to quantify the multiplier effect or the number of

legal immigrants gaining admission subsequently through their family relationship to an original immigrant (Jasso and Rosenzweig 1986, 1990). The magnitude of this legal chain migration would depend not only on individuals' interest, motivation, and behavior but also on the opportunity structure for legally immigrating to the United States. The present report does not explicitly address multiplier effects or chain migration except in addressing the possible magnitude of compositional shifts by authorization status in the near term as a consequence of the amnesty programs in the late 1980s with new analyses pursuant to Woodrow-Lafield (1995b). The major unit of analysis in this study is individuals, although amnesty-related family effects are indirectly noted.

Event Categories

Previous work has reviewed administrative data sources, statistical systems, and census and survey sources relevant for measuring or describing migration generally or authorized immigration in particular for the U.S. context (Levine, Hill, and Warren 1985; Kraly 1986; Jasso and Rosenzweig 1987). The discussion here cannot be exhaustive and is intended as a cohesive presentation of data and statistics for measuring and describing authorized immigration to the United States as to either gross or net magnitude. Although seemingly superfluous after previous sections on conceptualization and operationalization, explicitness as to terminology or nomenclature is necessary due to the character of administrative data systems or structures from which these statistics are derived.

First, individuals who have been lawfully accorded the privilege of residing permanently in the United States, and are presumed as settling, are known as *immigrants* in INS terminology. They may have been issued immigrant visas by the Department of State overseas and appear in official statistics as arrivals. Alternatively, they may already have legally entered the United States, usually on a nonimmigrant visa, and have their status adjusted to permanent resident status by the INS, filing an I-485 form. These individuals have experienced a status transition without having experienced a migration event. The descriptive "legal" is often used because the regular definition of "immigrant" does not prescribe legal status.

Effective as of fiscal year 1995, Congress added Section 245(i) to the Immigration and Nationality Act, which allows aliens who are living in the United States without authorization, but who have become eligible to acquire immigrant status, to apply directly with the INS rather than to return to the U.S. consulate abroad through which their visa application had been filed. The largest impact of this shift in application process may occur in the categories exempt from numerical limitation, such as immediate relatives of U.S. citizens (U.S. Immigration and

Naturalization Service 1996a; U.S. General Accounting Office, 1995a). This policy will be short-lived, however.

Second, the category of temporary, authorized migrants is found in INS statistics for *nonimmigrants, aliens who seek temporary entry to the United States for a specific purpose*. To receive such entry, nonimmigrants must have a permanent residence abroad and be approved formally for a nonimmigrant classification such as foreign government official, visitor for business or for pleasure, alien in transit throughout the United States, treaty trader or investor, student, international representative, temporary worker or trainee, representative of foreign information media, exchange visitor, fiancé(e) of U.S. citizen, intracompany transferee, or NATO official. Purposes for nonimmigrants' entries are usually related to work, business, education, or recreation and their visits are accordingly authorized for limited durations, usually with an explicitly stated deadline for departure.

Third, there are special categories of temporary and legally resident individuals given the nomenclature of nonimmigrant for which statistics are handled separately from the official nonimmigrant statistical structure. These are refugees, asylees, parolees, withdrawals, stowaways, and crewmen, of which refugees number the largest. *Refugee status* is granted to "any person who is outside his or her country of nationality who is unable or unwilling to return to that country because of persecution or a well-founded fear of persecution, based on the alien's race, religion, nationality, membership in a particular social group, or political opinion." Their case is special in that refugees are permitted to adjust to permanent residence after one year of continuous presence in the United States. *Asylee* refers to "an alien in the United States or at a port of entry unable or unwilling to return to his or her country of nationality, or to seek the protection of that country because of persecution or a well-founded fear of persecution." The bases are similar to those for refugee status and asylees are also able to adjust status after one year subject to numeric limitation (now 10,000 annually). *Parolees* have not been admitted formally to the United States and may be required to leave when the emergency (humanitarian) conditions supporting their parole into the United States cease to exist.

Similarly, generally *legalized aliens* are a unique, historical group who hold or held a temporary status before progressing to permanent residency (most in 1988-1990. These individuals were certain aliens who had been unauthorized or undocumented workers or were here as unauthorized or undocumented residents and were eligible to apply under the legalization provisions of the Immigration Reform and Control Act of 1986 (IRCA). To be eligible under the general amnesty provisions (filing I-687 application forms), aliens must have entered the United States before January 1, 1982 either (1) illegally or (2) as temporary visitors with

their authorized stay expiring, or with the Government's knowledge of their unlawful status, before that date, must have continuously resided in the United States in an unlawful status since before January 1, 1982, and must qualify for admission as nonexcludable. Another group of beneficiaries of amnesty under IRCA were agriculturally legalized aliens gaining *Special Agricultural Worker (SAW)* status (filing I-700 application forms) under an IRCA provision applicable for aliens who had performed labor in perishable agricultural commodities for a specified period of time during 1984-1986. The temporary and permanent statuses for agricultural legalization applicants will be discussed later.

Immigrants

Demographic characteristics, nationality, country of birth, and country of last residence encompass much of the heterogeneity of legal immigration over time. For the post-1965 period dating from initiation of the seven-category preference system for relatives of U.S. citizens and permanent resident aliens and for persons with needed skills and training, legal immigrants can be detailed as to whether an original immigrant or a non-original immigrant, that is, sponsored by a relative. Beyond this classification, legal immigrants can be classified as to whether a principal beneficiary immigrant or a derivative beneficiary, that is, a spouse, minor child, or unmarried adult son or daughter of principal immigrants as well as by preference category of admission or immediate relatives category.

The panorama of legal immigration to the United States is rich in descriptive detail by country of last residence from 1820 and country of birth from 1925. The availability of a consistent series of micro-data public-use immigrants files from 1972 to 1995 has enabled researchers to pursue studies of trends and contemporary issues (Greenwood, McDowell and Trabka 1991; Houston, Kramer, and Barrett 1985). Mexican immigration became visibly greater around the turn of the century during the great European migration over 1880-1920. By the time of passage of the 1965 Amendments, immigration from Mexico (as the country of last residence) already represented a substantial share of all legal immigration and has persisted in relative importance to other source countries despite the imposition of per-country limits under the preference system (Massey 1995, 1996). The European countries' share also diminished in recent decades, as there were large refugee and family migration flows from Asian countries in the 1970s and 1980s. Mexican immigration has long exceeded the preference per-country level due to admissions levels under immediate relatives provisions. The prevalence of Asians, Mexicans and other Latin Americans among legal immigrants is likely to persist unless the legal system is changed or the sending countries become more attractive than the United States.

Figure 1. Legal Immigrants Admitted from Mexico, Europe, and Total, 1821–1995

The legal immigration flows from Mexico have included large numbers of women and children for decades (Houston, Kramer, and Barrett 1985), reflecting that Mexican settlement in the United States is very family oriented, as is much of immigration from the rest of the world, rather than for simply labor reasons. There are some admissions of Mexicans under labor-based categories every year, but most admissions under the preference system are family-based.

Nonimmigrants

The arrivals and departures of nonimmigrant aliens, except students, have been processed through the Nonimmigrant Information System (NIIS) since 1984, a data system based on the arrival-departure form (I-94) completed by most aliens arriving by air or sea at ports of entry. INS collects the arrival portion at the time of inspection with the alien retaining the departure portion, attached to the passport, until collection by transportation carriers upon departure from the United States. The Student/Schools Data System tracks admissions, enrollments, and departures of students who are pursuing a full course of study in an approved program in an academic, vocational, or other recognized nonacademic institution.

Arrivals statistics are published regularly that show admissions by country of citizenship, port of entry, and nonimmigrant class of admission. Most nonimmigrants are admitted for a period of six months or less, and depart accordingly, but many other nonimmigrants live in the United States for several months or years on one or

more nonimmigrant classes. The INS has recently initiated publication of departures statistics. Recent statistics on immigrants show that about 40 percent are adjustments of nonimmigrants rather than new arrivals and two-thirds of immigrant adjustees show durations of stay exceeding one year. About 4.3 percent of adjustments in 1994 were for Mexicans. Among Mexican nonimmigrants adjusting in 1994, the majority were here with tourist visas.

Generally Legalized Aliens

A lengthy period of legislative debate culminated in IRCA's major amnesty program beginning May 1, 1987 for aliens who had been continuously resident in an unauthorized or undocumented status since before January 1, 1982 (Greenwood and McDowell 1985). The actual entry event was recorded on the I-687 application form filed in 1987-1988. These individuals' migration histories include the unique set of administrative events: the I-687 application, legalization approval for temporary residence status, and adjustment to lawful permanent resident. These administrative events redefine the authorization status of this population subgroup over time.

With some minor exceptions, the legalization program is regarded as a very successful endeavor on the part of INS. The agency effectively mobilized community groups, advocacy organizations, media resources, and its own staff to inform aliens, process applications in a timely manner, and provide assistance and decisions. Informal information networks played a significant role (Hagan and Baker 1993). Furthermore, the approval rate was very high as INS broadly interpreted documents as evidentiary of continuous U.S. residence. One empirical indication of a continued unauthorized or undocumented presence was that at least 700,000 were living within households of legalized aliens in 1988 (U.S. Immigration and Naturalization Service 1992a), but that figure declined by 1992 (Woodrow-Lafield 1994a, 1995b).

The best gauge of the amnesty's success would be a high rate of application among the long-term unauthorized or undocumented residents who were eligible. From evidence on the size and growth of the unauthorized or undocumented population (Passel and Woodrow 1986, 1987), the upper limit on the size of the amnesty-eligible population ranged between 2.5 and 4.0 million. INS used a similar range and drew on geographic-based research (Passel and Woodrow 1984b) to devise the geographic location of legalization offices. If the lower maximum limit from Passel and Woodrow's range were presumed, more than three-quarters of eligible aliens may have applied. Mexico was the single largest country represented among 1.8 million general legalization applicants as of May 1991; 1,229,016 were from Mexican aliens with 1,132,351 having entered without

inspection. The legalization brought greater numbers in Texas than anticipated but, on the other hand, the numbers of legalizations were somewhat disappointing for New York officials.

Published immigrants statistics for 1989-1996 (U.S. Immigration and Naturalization Service 1990, 1991, 1992b, 1993, 1994, 1995, 1996a, 1997b, 1997c) include legalized, generally and agriculturally, immigrants having adjusted status to permanent residence after the requisite residency period. The application period for the general program ended May 31, 1988, but INS continues to make decisions on some applications every year in the course of litigation. Several hundred thousand persons are participants in a class action case against INS to ask for the right to apply for the amnesty program. Most were unable to do so in 1987—1988 because their unauthorized or undocumented status may have been unknown to the INS. As some of these cases are resolved on an individual basis, additional legalizations are occurring.

The micro data public-use immigrants files do not include the legalization immigrants' records in keeping with the confidentiality provisions of IRCA.[1] However, the INS released administratively based micro data files including selected application items (including demographic and origin characteristics) and administrative processing information about the generally legalized and agricultural worker applicant pools (Borjas and Tienda 1994; Neuman and Tienda 1994). To meet mandatory reporting requirements of IRCA, the INS was the primary sponsor of the Legalized Population Survey (LPS) in 1989-1990 (U.S. Immigration and Naturalization Service 1992a). Another wave in 1992 (LPS2), primarily sponsored by the U.S. Department of Labor (1996), acquired post-legalization characteristics for individuals, their household members, and their family networks abroad.

Special Agricultural Workers

Under IRCA's provisions, aliens who had worked in seasonal U.S. agricultural services for at least ninety days during May 1, 1985 to May 1, 1986 could apply for temporary resident status during the application period June 1, 1987 until November 30, 1988. Applicants who had also worked at least ninety days during each of the two previous years (May 1, 1983 to May 1, 1985) could qualify as "Group I" applicants with entitlement to adjust to lawful permanent residence after one year (sooner than for Group II applicants).

The demographic impact of this legalization has not always been well considered. There were approximately 1.3 million applications under the SAW provisions of IRCA as of November 30, 1988, greatly exceeding the expected numbers. Nearly all were under the category of "Group II," showing only evidence of having worked for ninety days in U.S. agriculture. The flow of applications was

at an escalating pace; about 700,000 SAW applications were filed in May 1988–November 1988 (498,000 in the *last two months*). As given in the *New York Times* (November 12, 1989), "estimates by Federal officials and immigration experts place the number of fraudulent applications at somewhere between 250,000 and 650,000." The issue of fraudulence dims with the realization that working in U.S. agriculture is an experience characterized by high turnover and extensive recruitment. Consequently, the high number of agricultural legalization applicants may reflect a tendency to underestimate the number of unauthorized or undocumented workers involved in agriculture in addition to some fraud (Martin 1990; Commission on Agricultural Workers 1992:67).

As of November 1989, INS had approved only 490,000 agricultural legalization applications. Only 35,000 had been denied at that point. Nearly one million agricultural legalization applicants received legal status on December 1, 1990. The majority of these becoming agricultural legalization beneficiaries were "approved" through INS' failure to deny approval. Another indication of visa-seeking behavior from aliens living here is that the high volume (more than 600,000) of registrations for the Replenishment Agricultural Worker program included many (532,000 or 87 percent) with return U.S. addresses (Commission on Agricultural Workers 1992:66). About 85,000 (or 14 percent of the overall number) claimed they were immediate relatives of IRCA legalization applicants or beneficiaries. None were admitted during the authorization period for the RAW program because agricultural labor shortages did not materialize.

Published tabulations describe the agricultural legalization applicant population and statistics for adjustment to lawful permanent resident status in 1990 and 1991 reflect agricultural legalization beneficiaries (U.S. Immigration and Naturalization Service 1991). As for generally legalized immigrants, the agriculturally legalized cases are excluded from the public-use micro-data immigrants files and administratively-based public-use micro data files are the single source for their demographic characteristics, application information, and processing history.[2] There have been no survey efforts focusing on agricultural legalization applicants or beneficiaries, although the LPS identified some agricultural legalization beneficiaries living with generally legalized respondents (78,000) (U.S. Department of Labor 1996; Woodrow-Lafield 1995b, 1996b).

Refugees, Parolees, and Asylees

The U.S. Bureau of the Census includes some refugees in official accounts at the time of their arrival on the basis of data from the Office of Refugee Resettlement in the Department of Health and Human Services. Others, generally from countries sending few, are not added routinely at arrival, but they (and other nonimmigrants

living here including asylees) eventually appear in official INS statistics upon adjustment to permanent residence. Over recent years, several hundred thousand persons sought asylum in the United States, but the INS could not process their applications on a timely basis. Until very recently, this applicant pool constituted a significant population of indeterminate status.

Other Nonspecific

There are several additional special categories of foreign-born persons who are either legally present or of indeterminate status. Although several of the migration events discussed earlier are quite clearly to be considered as contributory to the permanently resident population, others may also be associated with permanent migration in more diffused ways.

Temporary Protected Status (TPS) was extended under the Immigration Act of 1990 to 194,000 Salvadorans here in January 1, 1991–June 30,1992, with later extension to additional aliens from Kuwait, Lebanon, Liberia, and Somalia, receiving this status due to country conditions deemed to prevent safe returns. A related program granted *de novo* affirmative asylum interviews to as many as one-half million Salvadorans here as of September 19, 1990 and Guatemalans here as of October 1, 1990 under the settlement of *American Baptist Churches vs. Thornburgh*. The initially specified date of departure has been deferred recurrently by request of the Salvadoran government and others (U.S. Commission on Immigration Reform 1994:162-173). They may wish to seek lawful permanent residence now that they have lived here for so long. Extended Voluntary Departure (EVD) status is granted to designated nationals in the United States because the U.S. State Department judged conditions in the countries "unstable" or "uncertain" or to have shown a pattern of "denial of rights."[3] Nearly all aliens from the People's Republic of China here at the time of the Tiananmen Square protests were eligible for deferred enforced departure upon visa expiration[4] and many later adjusted status (e.g., under the Chinese Student Protection Act).

Spouses and children of legalization beneficiaries are potentially resident without having lawful status. Under application guidelines, family members could submit all of their I-687 applications with a single fee of $475 rather than individually with fees of $150. About two-thirds of all primary applications were filed on this basis. Yet only about 451,000 (21.4 percent) of a total 2,111,000 nuclear family members of generally legalized persons had also attained amnesty (Woodrow-Lafield 1995b). Some were otherwise legally entitled to remain in the United States permanently with lawful permanent residence (135,000 or 6.4 percent), U.S. citizenship (1,133,000 or 53.6 percent), or SAW status (32,000 or 1.5 percent). However, approximately 107,000 or 5.1 percent gave "family fairness" or "family

unity" as their status, a reference to INS' policy that emerged to avoid family disintegration if some members were ineligible to apply under IRCA legalization provisions. The Immigration Act of 1990 remedied this "family unity" problem by allocating visas for dependents of IRCA legalization beneficiaries.

Populations

The "Standard"—Legally Resident Foreign-Born Population in 1980

Warren and Passel approached the task of estimating unauthorized or undocumented aliens as a function of nativity and citizenship. That is, they constructed an estimate for legally resident aliens and an estimate for aliens counted in the census, which involved an increase for aliens misreporting as naturalized citizens based on an independently constructed estimate for the naturalized citizen population.

Resident Aliens

For several decades, the INS maintained the Alien Address Registration System, on the basis of aliens' voluntary registration through the U.S. Postal Service annually in the entire month of January. The I-53 form contained only a few demographic and immigration items, including current address, category and date of admission, age, sex, and country of birth. The data were intended for INS resource allocation and statistical purposes and provided a periodic description of the origin, geographic, demographic, and status characteristics of the alien presence in the United States. As an economy measure, the Congress discontinued funding the program after 1981. Warren and Passel (1983, 1987a, b; Passel and Robinson (1988) first formulated a baseline estimate for the alien component using the Annual Alien Address Registration Program for January 1980. This initial estimate included or excluded categories of aliens according to self-reported resident status. Those categories considered "usually" resident by census residence rules are permanent resident aliens, students, refugees, and "other" aliens. Excluded categories included commuter workers, visitors, crewmen, and exchange aliens. Since registration was voluntary, an assessment of country-specific coverage was made by analyzing permanent resident alien admissions and the numbers of registered aliens for 1965-1980. The 1980 alien data were adjusted for estimated underregistration of 11.1 percent, resulting in an overall increase of 12.5 percent. For Mexico, Warren and Passel estimated that 7.3 percent of legally resident aliens had failed to register (Passel 1991). Underregistration or undercoverage may not have been a serious obstacle for statistical research as believed (Levine, Hill, and Warren 1985:65; Jasso and Rosenzweig 1990; Warren and Passel 1983, 1987a, b).

Naturalized Citizens

Naturalization statistics represent those among legally resident foreign-born persons who are not as likely as those who have not naturalized to return migrate or otherwise leave the United States to reside elsewhere. For immigrants of many origins, U.S. naturalization necessitates relinquishing citizenship in one's origin country and any nationality rights. Parents may list their minor children on their naturalization form, and request a copy of the child's (ren's) certificate of derivative citizenship from the INS. Unfortunately, from a statistical perspective, many do not do so and even when such certificates are requested, INS data system capture may be incomplete. Thus, INS naturalization statistics do not completely cover the population deriving citizenship automatically upon naturalization of a parent.

An estimate of naturalized citizens in the 1980 census was based on both census reporting as naturalized citizens and a demographic estimate constructed by surviving naturalizing immigrants over time, as identified with INS administrative naturalizations statistics. Substantial overstatement of naturalized citizen status (843,000) was found and shifted into the "alien" category, including about 375,000 for Mexico-born. Criticism of this work on the basis of INS recorded naturalizations over 1960-1980 (Hill 1985) is separate from the undocumented results because classification by citizenship is unnecessary for derivation of undocumented estimates.

Gauging Quality of 1980 Estimates

The initial Warren-Passel estimate for 1980 of 12,084,000 legally resident foreign-born persons, including 7,816,000 aliens and 6,118,000 naturalized citizens was meant to represent the complete population of legally resident foreign-born persons as of January 1980. Included were 1,400,000 persons of Mexican birth, with 1,195,000 aliens and 205,000 naturalized citizens. An obvious weakness is an insufficiency of 1980 census data for the earliest entry period (before 1960) for all countries or regions other than Mexico. Because there would be negligible amounts of non-Mexican unauthorized or undocumented immigration prior to 1960, this research has emphasized the "Entered After 1960" population, with inclusion of Mexicans who entered pre-1960.

Other limitations of that estimate may derive from country-level adjustment for underregistration of legally resident aliens. First, there was no direct information with which to estimate underregistration levels by age, sex, or period of immigration. Second, underregistration levels for the permanent resident alien category were assumed to apply to temporary resident alien categories, such as students, refugees, and other aliens. The proportions of permanent resident aliens of the registered population considered resident for census purposes varied by country from 12.3

percent (Saudi Arabia) to 98.8 percent (Portugal). (For Mexico, the percentage was 98.3 percent.) Consequently, there could be error in the estimates by country if this assumption were flawed.

The nature of the data collection period, based on a one month-period, also raises concerns about the utility because the population estimate would probably overrepresent shorter durations and overestimate the population entered for the most recent time period. Hill (1985) raised questions about *overreporting* for Mexico, among other countries, possibly as a result of misreporting by temporary residents in the category for permanent resident.[5] Subsequently, Passel (1991) allowed for greater variability in the legally resident alien component for the Mexican population (±10 percent) than for the non-Mexican population (±3 percent), noting that unauthorized or undocumented migrants might have erroneously registered.

Legally Resident Foreign-Born Populations Post-1980

Demographic Accounting

As described earlier, the estimate of legally resident foreign-born persons as of 1980 by Warren and Passel can be considered a "standard," in several senses, and it became a foundation for using a components-of-change method to derive post-1980 estimates for legally resident foreign-born populations in the United States. The major components of change are estimated mortality, assumed emigration, admissions of lawful permanent residents and certain groups of arriving refugees, and other transitions to lawful permanent residence by persons already living in the United States (including adjustments and legalizations). This methodology was designed for consistency with the Census Bureau's methodologies for demographic analysis and postcensal population estimates.

An accounting for components of change for the legally resident population had previously been implicit in accounting for change to the total resident population before 1980 because an unauthorized or undocumented presence had not been measurable for the 1970 census. The demographic analysis program for measuring U.S. census coverage relies on comparison of the enumerated population by age, sex, and race with an independently constructed estimate of the total resident population as of Census Day. However, the 1980 census apportionment counts delivered to the President January 1, 1981 exceeded the independent estimate, and Census Bureau demographers noted the possible effects for net undercount of one to six million unauthorized or undocumented residents (Passel, Siegel, and Robinson 1982). The ASA Technical Panel on the Census Undercount recommended in the fall of 1982 that the Census Bureau continue strong efforts to improve estimates of the number of illegal aliens and that the Census Bureau make public a sufficient

number of undercount estimates to illustrate the uncertainties in the methods (ASA Technical Panel, 1984). Plans for demographic analysis of 1990 census coverage recognized that demographic accounting for the total resident population must be legal status-specific. (See Himes and Clogg 1992.) To this end, a systematic research program at the Census Bureau monitored net authorized immigration in the 1980s and indirectly monitored net unauthorized or undocumented migration by partitioning foreign-born estimates into authorized and unauthorized or undocumented components (Passel and Woodrow 1987; Woodrow, Passel, and Warren 1987; Woodrow and Passel 1990; Woodrow 1992c).

Table 1 summarizes the 1970-1990 time series of estimates of foreign-born population, legally resident foreign-born estimates, and estimates of unauthorized or undocumented residents in surveys or censuses.[6] The measured number of unauthorized or undocumented residents in censuses or surveys has been around 2 million with the single exception of 1986 when the estimate was 3.2 million. The landmark amnesty of IRCA for aliens proving continuous residence in an unauthorized or undocumented status since January 1, 1982 generally confirmed the various studies (Warren and Passel 1983, 1987a; Passel and Woodrow 1984b; Meissner and Papademetriou 1988). Post-1986 estimates required accounting for IRCA-legalized aliens' transitions from unauthorized or undocumented resident to authorized `or legal resident. Those legalizing on the basis of having lived here continuously in an undocumented status since before 1982 are *prima facie* permanent residents. These figures in Table 1 incorporate most of the general legalizations, but alternative estimates based on allowing for agricultural legalizations are discussed below (Woodrow and Passel 1990; Woodrow 1992c). IRCA's amnesty appeared to result in a marked decline in the "enumerated" unauthorized or undocumented resident population between 1986 and 1989, but levels of net unauthorized or undocumented migration were undiminished (Woodrow and Passel 1990; Woodrow 1992c; Donato, Durand, and Massey 1992).

Because the U.S. Bureau of the Census does not officially measure undercoverage of the foreign-born population in total or by legal status, a potpourri of rationales have been discussed for a range on the total number of unauthorized or undocumented residents over 1980-1990. Despite the passage of time, these ranges are not really very different. The most consensual is the range for 1980 that relies on several studies suggesting that the probable upper bound of the unauthorized or undocumented population was 3.5-4.0 million (Bean, King, and Passel 1983; Levine, Hill, and Warren 1985; Passel and Robinson 1988; Heer and Passel 1987). Following some internal wrangling between demographers and statisticians about the quality of residual estimates for unauthorized or undocumented residents, the Census Bureau used 3.0 million as the preferred estimate for total net unauthorized or undocumented migration as of 1980 (Fay, Passel, and Robinson 1988), of which

Table 1
Estimates for Foreign-born, Legally Resident, and Unauthorized Populations Based on Demographic Accounting: 1970–1990

Date of Estimate	Foreign-born in census or survey			Legally resident foreign-born in U.S.		Estimated unauthorized residents in survey or census	Hypothetical total number or range (in millions)	Relevant Sources
	All Periods	%	Post-1960	All periods	Post-1960

Note: Most foreign-born population figures include estimated amounts for misreporting as native foreign-born persons.

Source: Woodrow-Lafield, Forthcoming

2.3 million represented net unauthorized or undocumented migration for the 1970s (Passel and Robinson 1988).[7]

These studies were the foundation for the net unauthorized or undocumented migration component for evaluating the 1990 census (Woodrow 1991a) discussed below. For this evaluation of 1990 census coverage (Robinson et al. 1991, 1993), an estimate for legally resident foreign-born population was implicit rather than explicit and the net "unauthorized or undocumented" migration component possibly included agriculturally legalized residents. Interpretation of the transition of agriculturally-legalized (SAW) applicants has never been clear whether the time-referent were 1988, 1989, 1990, or today. Throughout discussions of post-1980 analyses, application of the components-of-change method is complicated by, first, the legal precariousness of agricultural legalization applicants and, second, by attribution of U.S. residence for agricultural legalization-approved beneficiaries. The last two studies mentioned in this table (Woodrow-Lafield 1995a; Clark et al. 1994) make allowances for nonspecific authorized immigration, including agriculturally legalized residents, and we return to these results following discussion of unknown factors in measuring net authorized immigration and a closer examination of studies for the 1979-1989 period.

Mexican population estimates for national surveys, including the 1970-1990 censuses, are shown in Table 2, as available on a comparative basis using similar residual methodologies. The legally resident Mexico-born population in the United States increased from about 1.4 million in 1980 to perhaps 3.0-3.5 million for 1990, depending on particular assumptions. This increase mirrors the overall increase over recent decades in the size of the Mexico-born population living in the United States. The unauthorized or undocumented population of Mexican birth appears to have fluctuated and to have declined slightly for 1990 relative to 1980, but this appearance may be merely artifactual due to the unauthorized or undocumented estimate as a residual using the survey or census estimate subject to undercoverage. Prior to IRCA, extrapolation of studies of average population change due to net unauthorized or undocumented migration from Mexico implied there were as many as 2.5 to 3.5 million unauthorized or undocumented Mexican residents (Passel and Woodrow 1987).

These estimates for legally resident foreign-born populations are only as accurate as they are unbiased from data gaps on emigration or return migration and unknown long-term immigration associated with nonimmigrants or agriculturally legalized persons. Exercising expert judgment is inescapable, but guiding strategies are nonexistent. The number of unauthorized or undocumented residents in 1990 was certainly below six million (Woodrow-Lafield Forthcoming). The next section addresses the more "known" components of change. The following sub-sections address the major uncertainties about the authorized foreign-born estimate stemming

Table 2
Estimates for Foreign-born, Legally Resident, and Undocumented Populations from Mexico Based on Demographic Accounting: 1970-1990

Date of Estimate	Mexican-born in census or survey			Hypothetical total number or range (in million)s	Source for undocumented
	Total	Legally resident	Undocumented		
1970 Census	789,000	789,000	0	Fewer than .333	Passel & Robinson (1988)

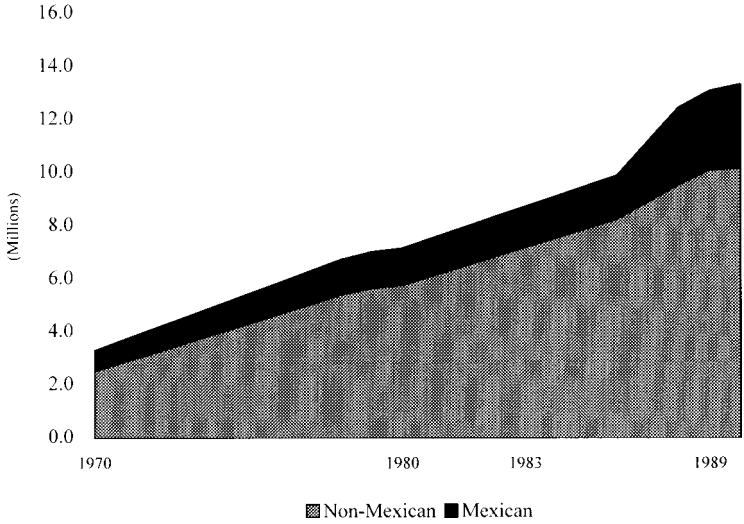

Figure 2. Legally Resident Foreign-born by Mexican Birth: 1970–1990

from "temporary" migration, emigration after authorized immigration, incorporation of the agriculturally-legalized population, and the ultimate immigration consequences of the IRCA legalizations.

Knowns: Administrative Statistics

Admissions for lawful permanent residence, legalization approvals, adjustments to lawful permanent residence, and nonimmigrant arrivals are easily accessible administrative statistics. These would be considered "knowns" in the sense that the data sets are regarded as highly complete within the domain. Interpretive cautions must be noted for using these administrative statistics for social science research. First, those immigrants arriving as permanent residents may have had prior U.S. residence experience or may anticipate short or long stays abroad. Survey responses to questions about the timing of immigration may differ from recorded date of lawful permanent residence. Second, generally-legalized immigrants are usually presumed as having settled here for their lifetimes and at minimal risk of return migration as a consequence of their sustained presence. Third, those adjusting to lawful permanent residence from a nonimmigrant class may have substantial U.S. residence histories, either continuous or on an intermittent basis. Fourth, arriving nonimmigrants are presumed to be temporary residents, and the majority of nonimmigrant departures occur following short durations of stay.

Unknowns: "Temporary" Migrants

A one-year entry cohort of nonimmigrant arrivals[8] is comprised of (1) aliens who ever depart and (2) aliens who stay or are lifetime migrants. Among those who depart, most do so after a brief visit, as is the experience for the majority of arriving nonimmigrants, and others depart after stays of one year or more. Among those who stay, some adjust to permanent resident status and others stay as unauthorized or undocumented, but either may have changed among nonimmigrant classes. Those nonimmigrant arrivals followed quickly by departure are not considered as counting toward population change and such individuals would not meet residence rules for either census enumeration or inclusion in national surveys. Those eventually departing after longer residence periods and those ultimately becoming lawful permanent residents present difficulties for accounting for population by authorization status. The magnitude of the accumulated number of present stayers across various nonimmigrant arrival cohorts is needed to estimate the legally resident foreign-born populations for dates falling within the transition between nonimmigrant status and departure or adjustment to permanent status. Ultimately, a stayer's presence is recorded in immigrants statistics for adjustees and the rest depart. If the population were constant over time, there would not be a problem.

This problem is difficult conceptually, analytically, and empirically. The appropriately detailed arrivals and departures statistics are not yet published for monitoring the nonimmigrant population, although considerable improvements have been made. Departures statistics have not been published regularly and are incomplete because the departure portion of the I-94 form may not be collected at exit or INS may receive it much later. In reviewing relevant studies, four questions are posed: (1) As of a specific date, how many nonimmigrants have stayed in the United States for at least one year *or are likely to do so*? (2) How many nonimmigrants have stayed in the United States for at least one year as of a specific date? (3) How many nonimmigrants among those arriving within a year stay for at least one year before their departure? (4) How many nonimmigrants would stay for at least one year for a hypothetical arrival year? The net difference of 2.3 million for 1994 (22.1 million arrivals less 18.8 million departures) cannot be interpreted as answering any of these questions. The first two questions could be phrased with respect to 1990 and 1995 or 1996 dates for the overall purpose. The latter two questions are more flow-oriented. Modeling nonimmigrant processes of arrival, departure, and adjustment over time with modification for departures' undercoverage could address these questions.

The first question is relevant for gauging how many nonimmigrants may be included in a census or national survey of the resident population. The residence rules for the census stipulate that individuals should be living here on a permanent

basis or should have lived here for at least six months. Even when migration may not be for permanent residence, six months of residence might be considered a threshold for considering nonimmigrants as usual residents. The 1980 estimate of Warren and Passel included about 612,000 nonimmigrants whose class of admission was taken to imply "usual" residence—243,000 refugees, 192,000 students, and 177,000 other aliens (Woodrow 1990). Throughout the 1980s, official postcensal population estimates did not allow for population change due to temporary migration, i.e., depending on the presumption that newly arriving nonimmigrants becoming "usual" residents for several months or years would be offset by departures, including adjustments of status of similarly usually resident nonimmigrants.

From several indications, the size of the nonimmigrant population stock is likely to have increased. One set of consequences for the "black box" of nonimmigrant stayer is the volume of adjustments to lawful permanent residence. A total of 1,150,000 long-term nonimmigrant residents, excluding IRCA adjustees, adjusted to lawful permanent residence during 1990-1994 or about 230,000 annually. This is considerably greater than for 1980-1984. Without knowing the size of the nonimmigrant stock now, one could retroactively impute its value on the basis of those giving the designated date or an earlier date of entry upon adjusting in subsequent years. The volume of nonimmigrant arrivals nearly doubled for 1981-1990 (123.1 million) relative to 1971-1980 (64.3 million). Over 1985 and 1994, the numbers of nonimmigrant arrivals increased from 9.5 to 22.1 million. Having established that contemporary measures for the nonimmigrant stock are necessary, there are none in the absence of the alien registration program. Such an accounting could have been accomplished in the course of another statistical program to measure visa overstay levels. Several studies (Warren 1986, 1990, 1993, 1994a) have focused on inferring the contributions of nonimmigrant visa overstays to net unauthorized or undocumented migration. The same analytic strategy could emphasize measurement of contributions of nonimmigrant visa stays to net authorized immigration.

The empirical evidence as to the third question is limited to a single case study of nonimmigrant arrivals during calendar 1983 that resulted in a departure before 1988. Kraly and Warren (1991, 1992) estimated long-term immigration including not only lawful permanent resident statistics but also allowances for nonimmigrant arrivals with eventual departures after a one year stay as of 1987 and for nonimmigrant arrivals with eventual adjustment to lawful permanent residence during 1984-1986. These studies by Kraly and Warren (1991, 1992) rely on *ex post facto* definition of nonimmigrants as long-term immigrants. Among all nonimmigrant arrivals (9,849,000), the majority departed within the first year, but about 113,000, or 1.2 percent, departed after at least a one-year stay (Kraly and Warren 1991). Among those from Mexico (627,000), about 7,000, or 1.1 percent, departed after one year

or more. Nonimmigrant arrivals under classes of foreign officials, temporary workers, exchange visitors, refugees, and students, showed higher percentages of long-term stays leading to departures than for visitor classes. Another 79,000 persons who initially arrived as nonimmigrants in 1983, of whom 5,000 were from Mexico, adjusted to permanent resident status. These statistics are right-censored as to departures after 1987 and permanent residence adjustments after 1986 (or the extent that all departure forms may not have been collected) (Kraly and Warren 1992). With more complete data for 1987, Kraly and Warren (1992) reported that long-term immigration reached 120,000 (including 8,000 from Mexico) and adjustments reached 96,000 (including 6,000 from Mexico). According to my own examination of 1988-1994 statistics, adjustments to nonimmigrants arriving in calendar 1983[9] were 9,093, 14,905, 29,683, 41,516, 7,553, and 2,683 for Fiscal Years 1988-1993 (including 561, 556, 8,226, 21,152, 26,839, and 3,092 from Mexico).[10] Longer observation for this transition would minimize right-censoring biases on long-term immigration measures.

The fourth question concerns nonimmigrants living in the United States in a hypothetical sense. To illustrate a technique for projecting the amount of long-term immigration associated with more recent nonimmigrant arrival cohorts, Kraly and Warren (1992) showed duration-specific proportions departing or adjusting to permanent residence for nonimmigrant arrival cohorts of 1983-1987.[11] Such a set of rates could be used to generate synthetic estimates for this additional components of long-term immigration for any year subject to applicability for other nonimmigrant arrival cohorts. The duration-of-stay statistics in U.S. Immigration and Naturalization Service (1996b) can be used to generate a hypothetical distribution of person-years in the United States for any departure cohort, but these statistics are not necessarily descriptive of any particular arrival cohort.

Unknowns: Emigration after Permanent Authorized Immigration

Following the post-war period of low immigration and low emigration, the volume of authorized immigration rose over the 1960s, 1970s, and 1980s. The magnitude of emigration after authorized immigration, also known as return migration or re-migration, began to shift upward. Absent official counts for departing immigrants, several studies using indirect approaches have described possible emigration levels for the 1960s, 1970s, and 1980s decades (Warren and Peck 1980; Warren and Kraly 1985; Warren and Passel 1987b; Woodrow-Lafield 1996a; Ahmed and Robinson 1994; Borjas and Bratsberg 1996).

The crucial question is whether emigration has perpetually increased in the latter half of the 20th century as the foreign-born population increased dramatically.

Emigration levels for 1960-1990 and 1960-1999 might be similar to levels over 1960-1980 if the propensity to emigrate may be lower among contemporary residents than among prior cohorts or because origin or other characteristics associated with lower propensity to emigrate may be more highly represented among the foreign-born recently residing in the United States. The compositional mix of the foreign-born population has shifted to include greater proportions of (1) Latin Americans and Asians for whom emigration has seemed lower than for Europeans (Jasso and Rosenzweig 1990; Warren and Kraly 1985) and (2) immigrants who entered under visa categories logically associated with lesser likelihood of return migrating, such as refugees, asylees, adjustees from nonimmigrant statuses, and formerly unauthorized or undocumented or temporarily resident individuals.

The empirical evidence is mixed as reviewed in Kraly (1997) and Woodrow-Lafield (1997). First, Borjas and Bratsberg (1996:169) found emigration for immigrants entering in the 1970s of about 900,000 by 1980, which equaled three-quarters of that for all period of entry groups found by Warren and Passel (1987b). This level for recent entrants' emigration may be overestimated by not allowing for 1980 census undercoverage. The range of total emigration for 1980 census coverage research was about .9 to 1.9 million foreign-born emigrants. Second, multiplicity sampling-based surveys of U.S. residents about nonresident relatives were fielded to measure emigration occurring over 1980-1989 (Woodrow-Lafield 1996a). Because the emigrant population is relatively small, the survey estimates are subject to considerable sampling variance. Based on these results and sensitivity analyses using emigration rates by age, sex, period of entry, and country or region of origin, the preliminary 1990 census coverage evaluation employed an estimate of 1.33 million for net emigration of legally resident foreign-born for the 1980s and allowed a range of .8 million to 2.2 million (Woodrow 1991b). An intercensal approach (as in Warren and Peck 1980) yielded a result toward the upper end of this range (Ahmed and Robinson 1994) suggesting higher emigration in the 1980s than in the 1970s. A higher emigration allowance was adopted for population programs in the 1990s, but the effect was offset by an increased allowance for net population change due to net unauthorized or undocumented migration. Two methodological questions concern comparability of coverage in the context of rising nonimmigrant arrivals and continuing unauthorized or undocumented immigration and the validity of assuming similar propensities to emigrate for pre-1980 immigrants and post-1980 immigrants within age, sex, and country of birth subgroups. These points are considered at length in Woodrow-Lafield (1997) and Kraly (1997).

The preponderance of evidence about emigration is more adequate for positing a broad range than for stating that emigration levels are higher in the 1980s or 1990s than in the 1970s. For the purposes of estimating net authorized immigration as of the 1980s and 1990s, assumptions about the level and composition of

emigration flows are generally consistent with prior research for the 1960s and 1970s. For post-1989 analyses, alternative series show the effects of varying annual emigration among 95,000, 133,000, or 195,000. Compositional detail by age, sex, and period of entry would be tenuous. The studies by Woodrow and others (Woodrow, Passel and Warren 1987; Woodrow and Passel 1990; Woodrow 1992c) using independently constructed estimates for the legally resident foreign-born population in the 1980s did not produce age and sex detail with the exception of Passel and Woodrow (1987). Legal foreign-born emigrants will be distributed to Mexico as country of origin and to all other countries of origin on the basis of Warren and Kraly (1985) as for unauthorized or undocumented research (Woodrow and Passel 1990; Woodrow 1992c).

The Mexico-born population has increased dramatically since 1950, but that increase has been dominated by authorized immigration—primarily family-based and legalization-based. The current magnitude of the Mexico-born population poses conflicting expectations about return migration levels. In one sense, there might seem to be lesser propensity for return migration given a greater density on authorized status, greater demographic diversity, and possibly greater representation of sending communities at migration maturity. Alternatively, the Mexico-born population accumulated over entry cohorts of the 1970s, 1980s, and 1990s could be approaching a "critical mass" for return migration when Mexican return migration could become more easily discernible, despite limitations of methodologies. Such a shift would be detectable by comparing multiplicity sampling-based estimates of Mexican emigrants as Woodrow-Lafield (1996a) found for the post-IRCA period (e.g., 1988-1998 or 1988-2003).

Unknowns: U.S. Residence of Agricultural Legalization Beneficiaries

Meaningful distinctions exist among agricultural legalization applicants, agricultural legalization-approved beneficiaries, agricultural legalization-default beneficiaries, and residents becoming agricultural legalization-approved beneficiaries. The agricultural legalization beneficiaries may not be presumed automatically as living in the United States because their "proof" of agricultural work experience did not establish usual residence in the United States. As well known from studies based on the Mexican Migration Project, Mexican migration is a complex process. Within that data base, settlers abroad are defined on the basis of having a U.S. stay of at least three years. Because about 700,000 agricultural legalization applications were filed in May 1988-November 1988 (498,000 in the *last two months*), the agricultural legalization program may have been a magnet for aliens seeking U.S. residence status and may have ultimately promoted migration to and settlement in

the United States. (Also, see Martin 1990, 1994, 1996.) Further confusing the issue of whether agricultural legalization beneficiaries live in the United States, the INS automatically granted lawful permanent resident status to all agricultural legalization beneficiaries. That benefit was extended to both approved beneficiaries and default beneficiaries, whose applications INS simply failed to deny, with about 900,000 receiving approval and becoming "lawful permanent residents" by the default deadline of December 1, 1990.

Three sources offer some insights to the behavior of agricultural legalization beneficiaries following legalization. First, the National Agricultural Workers Survey (NAWS) acquired individual migrant workers' legal status; almost one-half of the migrant workforce in 1989—1991 had legalized under IRCA (Gabbard, Mines, and Boccalandro 1994).[12] Samardick (1995) reported that about 32 percent of Mexico-born migrant workers in 1993-1994 had SAW status and another 7 percent were general legalization beneficiaries. Many of the agricultural legalization beneficiaries appear to have continued working in seasonal agricultural services. Second, the numbers awaiting second preference visas for spouses and children of legalization beneficiaries as of January 1993, 1994, 1995, and 1996 exceeds the likely level for the generally legalized population (Woodrow-Lafield 1995b), suggesting that as many as one-half million are dependents of agricultural legalization beneficiaries. The third indicator of agricultural legalization beneficiaries' residence in the U.S. rather than their origin country will be their behavior in seeking to naturalize. All were eligible to begin to apply for naturalization on or before December 1, 1995. Naturalization applications for fiscal year 1996 were markedly higher for 1996 (1.2 million) over the previous year, but INS has not updated information about applications for naturalization among eligible generally legalized immigrants or agricultural legalization beneficiaries. As of May 1994, only 7.7 percent of eligible generally legalized immigrants (233,000) had applied to naturalize (U.S. Department of Labor (1996:107). Current levels of completed naturalization levels would help in inferring U.S. residence for agricultural legalization beneficiaries.

Unknowns: Immigrant Flow Effects from IRCA

The U.S. presence of family members of IRCA beneficiaries must be viewed carefully in building an accounting model for the legally resident foreign-born population. The consequences of the general legalization program under IRCA will be considerable with as many as three million future immigrants related to these legalization beneficiaries, including at least one million Mexican relatives (Woodrow-Lafield 1994a). As noted above, many relatives were here with authorized permanent status. Approximately 136,000 spouses, 223,000 children, 30,000 parents,

130,000 siblings, and 102,000 other relatives were living in IRCA beneficiaries' households in 1992 and had nonresident statuses (family fairness, temporary visa, other, or missing). Within households of legalized Mexican immigrants, there were 91,000 spouses, 159,000 children, 19,000 parents, 99,000 siblings, and 69,000 other relatives in nonpermanent statuses, totaling 436,000 (unpublished analyses by Woodrow-Lafield). The problem of family disruption became apparent in 1987 with cases of families with members ineligible to apply for amnesty, leading to INS' policy known as "family unity" or "family fairness." The IA90 was an attempt to resolve these situations with up to 55,000 visas for spouses and children of legalization beneficiaries. A lesser amount resulted (140,000 and the second preference visa waiting list counts associated with legalization beneficiaries grew to 739,774 in January 1993 and remained high (853,382, and 824,000 in 1994 and 1995), including many spouses and children of agricultural beneficiaries (U.S. Department of State 1993, 1994, 1995; U.S. Commission on Immigration Reform 1995). Empirical evidence exists for the immigrant flow consequences from the general amnesty, but none exists for those from the agricultural legalization. Given the high level of uncertainty surrounding the agricultural legalization beneficiaries as possible U.S. residents, this additional data gap is very serious.

Waiting times for new applicants are growing progressively longer and approaching ten years' duration (U.S. Commission on Immigration Reform 1995). Resident dependents of IRCA beneficiaries will eventually be incorporated into future estimates for the legally resident foreign-born population as they become lawful permanent residents with allocated visas for 1992-1994, with second preference (or first, third, or fourth preference) visas in some year, or under provisions for immediate relatives (parents, spouses, or minor children) of U.S. citizens. To date, those from the first category and some of the second will be incorporated. Omission of others from the authorized estimate causes overestimation of an unauthorized or undocumented residual.

A more expedient way for the IRCA beneficiary to bring close family members as legal immigrants to the United States will be the two-tier processes of naturalization and sponsorship under numerically exempt immediate relatives provisions. Many of those who were minor children (100,000-200,000) at the time of visa petition filing may have aged into adulthood by the time of visa issuance and therefore be ineligible (U.S. Commission on Immigration Reform 1995). Among Mexican respondents in the 1992 LPS, nearly three-quarters indicated they would either "definitely" or "probably" apply for naturalization upon becoming eligible (Woodrow-Lafield 1995c). This study is consistent with microeconomic theory about naturalization decisionmaking in that having a coresident sibling without permanent status and having a parent or sibling intending to immigrate are significantly associated with intending to apply for naturalization.

If IRCA-legalized immigrants were able to complete the naturalization process easily and quickly, then the numbers of spouses and children who would become lawful permanent residents under immediate relatives' provisions during 1995-1998 would be approximately 300,000, considering Woodrow-Lafield's (1994a, 1995b) work, and if SAW-legalization immigrants were equally able to naturalize, the entire backlog of 824,000 might be converted into legal immigrants (if there were no aging of minor children). These figures could even be conservative because some naturalizing legalized immigrants may not have petitioned for their spouses' and minor children's admission under second preference, fearing that might jeopardize their chances of securing nonimmigrant visas for short-term visits. Probably some three-quarters of these various figures would represent Mexican origins. Two other plausible explanations for arguing that these figures may be conservative is that the empirical evidence omits future family unification to agricultural legalization beneficiaries and migration and U.S. settlement of agricultural legalization beneficiaries may be as lengthy as described in the work of Massey and others. It is conceivable that the visa waiting list under second preference could double or triple over the next few years.

Net Authorized Immigration for 1979-1989

The construction of the 1979, 1983, 1986, 1988, and 1989 estimates for legally resident foreign-born populations uses the 1980 base population and authorized immigrants by age group, sex, period of entry, and country of birth, with all survival calculations preserving this specificity. The decrements for emigration and increments for legalizations are made in the last stage by country of origin and period of entry. Illustrative increments for agriculturally legalized residents are by sex for Mexico and all other countries. The increment for generally legalized immigrants could more easily be made by age and sex than the increments for agriculturally legalized immigrants or immigrant flows from IRCA beneficiaries' sponsorship.

Published detail by estimated authorized status has always been restricted, whether to age groups, sex, country, and period of entry (Warren and Passel 1987a), broader age groups, country, period of entry, and state of residence (Passel and Woodrow 1984b), or period of entry and region of birth (Passel and Woodrow 1987; Woodrow, Passel, and Warren 1987; Woodrow and Passel 1990; Woodrow 1992c). The census-based studies carried risks of various estimation errors, which might be either independent or cumulative. The survey-based studies have the added limitations of sampling errors to prohibit highly detailed analyses of demographic and origin characteristics; therefore, demographic detail in studies after the 1980 census was incorporated for instrumental purposes rather than for its intrinsic value.

Without Accounting for IRCA Legalizations

Prior studies showed post-1986 estimates for the legally resident foreign-born population without any amnestied aliens pursuant to IRCA for estimating net population change due to unauthorized or undocumented immigration. Without allowing for legalizations pursuant to the amnesty provisions of IRCA, the foreign-born population legally resident would have grown from 7.0 million to 11.4 million over 1979-1989 (second tier, Table 3). This increase is only from post-1981 immigration. Recently admitted authorized Mexico-born immigrants accounted for slightly more than one-tenth of net authorized immigration for the post-1981 entry period.

With Accounting for Generally Legalized Immigrants

The featured or preferred estimates (first tier) for the legally resident foreign-born population showed an increasing trend over 1979-1989 from 7.0 million to 13.1 million. The rate of increase was greater for the legally resident Mexico-born population as the number more than doubled over that decade from 1,388,000 to 2,522,000. Without considering origin, most of the increase is attributable to post-1981 immigration. With closer examination, most of the increase for the Mexico-born population is almost wholly from the IRCA legalization of aliens proving continuous unauthorized or undocumented residence since before January 1, 1982. As a reminder, these estimates of the legally resident foreign-born population were produced under the auspices of the Census Bureau's 1980 and 1990 census coverage evaluation programs and, accordingly, are intended to represent those individuals meeting the Census Bureau's criteria for living in the United States on a usual basis.

With Incorporation Of Agriculturally Legalized Beneficiaries As Residents, Alternative Series

The issue of agricultural legalization applicants' inclusion in the legally resident estimate, in national surveys or the census, and in survey-based unauthorized or undocumented estimates was complicated during 1988-1990. For example, the review of the illegal immigration component by Himes and Clogg (1992) mentioned only the generally legalized immigrants. Until the deadline of December 1, 1990, the INS might have refused many of the applicants on the basis of having shown insufficient grounds. Making any allowance for agricultural legalization beneficiaries' residence affects primarily the overall legally resident foreign-born and legally resident Mexico-born populations.

Table 3
Estimates of Net Legal Immigration with Legalizations, 1979–1989, Total and Mexican-born

Data and Source	Total (in thousands)			Mexico-born (in thousands)		
	Total	Entered Before 1982	Entered After 1981	Total	Entered Before 1982	Entered After 1981
Preferred

Table 3 (Continued)

Data and Source	Total (in thousands)			Mexico-born (in thousands)		
	Total	Entered Before 1982	Entered After 1981	Total	Entered Before 1982	Entered After 1981
With general legalizations and nearly all SAW beneficiaries as residents						
1979, Passel and Woodrow (1987)	7,036	7,036	–	1,388	1,388	–
1980, Passel and Woodrow (1984)	7,173	7,173	–	1,400	1,400	–
1986, Woodrow, Passel and Warren (1987)	9,911	7,595	2,316	1,657	1,397	260
1988, Woodrow and Passel (1990)	12,473	9,114	3,359	2,985	2,597	389
1989, Woodrow (1991a, 1992c)	14,104	8,887	5,217	3,799	2,522	1,277

Post-1986 analyses included illustrative estimates based on alternative assumptions about inclusion of agricultural legalization applicants as legally resident for November 1989. The scenarios, similar to those presented in Woodrow and Passel (1990) and Woodrow (1992c), are:

- *Low* assumption of agricultural legalization beneficiaries as residents, for which each is assumed to have resided in the United States, on average, for three months, implying that 250,000 would be included;
- *Moderate* assumption of agricultural legalization beneficiaries as residents, for which each is assumed to have resided in the United States, on average, for six months, implying that 500,000 would be included;
- *High* assumption of agricultural legalization beneficiaries as residents, for which 550,000 beneficiaries (including 100,000 Group I and 450,000 Group II) are assumed as continuously resident in the United States and for which 450,000 beneficiaries are assumed to have resided in the United States, on average, for six months, implying that a total of 775,000 would be included;
- *All* assumption of agricultural legalization beneficiaries as residents, for which nearly all beneficiaries are assumed to have resided in the United States permanently, for inclusion of 1,000,000.

The effect of incorporating agricultural legalization beneficiaries as residents increases the post-1981 portion of net authorized immigration with especially marked increase for the Mexico-born population. The 1988 and 1989 studies also considered composition by sex with illustrative scenarios (Figure 3). Given implications for derivation of unauthorized or undocumented estimates, it appeared in the late 1980s

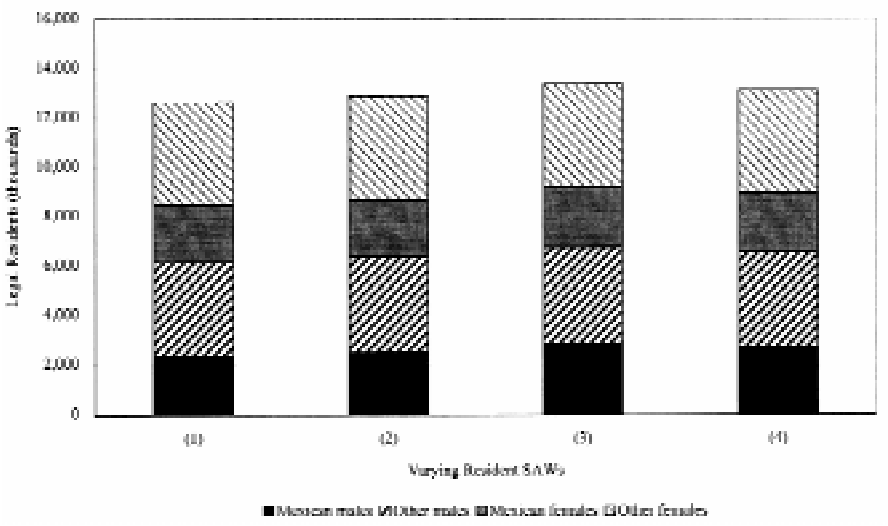

Figure 3. Legally Resident Mexico- and Other Foreign-born for 1989

as if the demographic and origin characteristics of the agricultural legalization applicant pool constrained the feasible assumptions at that time to low and moderate ones. Allowing for inclusion of more than 500,000 agricultural legalization applicants (perhaps 425,000 from Mexico) in the legally resident estimate led to unbalanced sex ratios and implausible unauthorized or undocumented estimates based on the 1988 and 1989 CPS (Woodrow and Passel 1990; Woodrow 1991a, 1992c). Some or many SAWs may certainly have been living in the United States prior to final INS processing and simply have been omitted from the CPS estimates of the foreign-born population. The likelihood of high census and CPS undercoverage for agricultural legalization beneficiary residents is obvious, particularly if they resemble agricultural migrant workers (Kissam 1993; La Cooperativa Campesina de California 1991; Gabbard, Kissam, and Martin 1993).

On an average annual basis, the combined unauthorized or undocumented and IRCA-legalizing population increased by about the same amounts among nearly all the time periods for all countries combined—approximately 200,000. For the various time intervals 1979 to 1989, 1979 to 1986, and 1986 to 1989, average annual change ranged between 163,000 and 218,000 (with confidence intervals bounded by 57,000 and 288,000). As apparent from Figure 4, if one abides by this range of variability, the amount of net population-level change due to unauthorized or undocumented immigration over the 1980s has considerable uncertainty. The decade's amount might have been about one-half million, or greater by a factor of five.

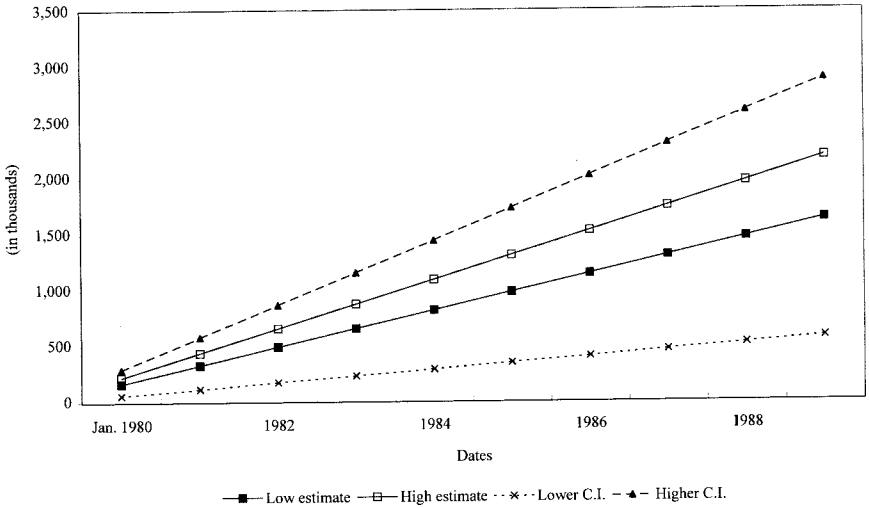

Figure 4. Net Population Change Due to Estimated Undocumented Immigration

Some authors have incorrectly given a range of 100,000 to 200,000 yearly as based on the Census Bureau's studies of population growth from unauthorized or undocumented migration for the 1980s (Simcox 1994; Warren 1994b). However, the range of 100,000 to 300,000 was consistently quoted for population-level change beginning with Passel and Woodrow's analysis (1987) for 1979-1983 corresponding with confidence intervals on estimates for annual change (Passel and Woodrow 1986; Woodrow 1992c:134). One explanation is that some readers may interpret the survey-based estimates too literally without heeding sampling errors. Alternatively, the misinterpretation may have happened when the population projections methodology (U.S. Bureau of the Census 1989) anticipated a post-IRCA decline as, apparently, even Congress believed there had been "significant progress" in closing Athe back door to illegal immigration@ (Day 1996:69). One must also be careful to recall that population estimates and projections, and the 200,000 allowed annually for change due to unauthorized or undocumented migration, are *only census-level*.[13]

Caveats

When considered independently of any survey evidence on immigrants, interpretation of net authorized immigration estimates require cognizance of only possible estimation errors with cumulative, rather than merely offsetting, effects.

Because these estimates were prepared for the purpose of monitoring unauthorized or undocumented immigration during the 1980s, other implications of measurement errors are relevant. Although drawn from non-survey sources, the methodology for deriving undocumented populations as a residual requires statistical significance testing as if legally resident estimates were included within the survey. The presence of sampling or nonsampling errors for certain subpopulations can be signaled by negative unauthorized or undocumented estimates as was the case for non-Latin American populations with the November 1989 analysis.

Net Authorized Immigration: 1990 and Beyond

For Census Day, 1990

Demographic analysis of 1990 census coverage estimated the total resident population at 253.4 million, including the unauthorized or undocumented population residing in the United States on April 1, 1990 by May 1991, prior to the Secretary of Commerce's decision on whether to adjust the 1990 census apportionment counts for undercoverage. However, demographers could not replicate previous analyses, that is, compare the legally resident foreign-born population estimate as of Census Day 1990 with the 1990 census count of the foreign-born population which was unknown until early February of 1992 and officially tabulated by 1993 (U.S. Bureau of the Census 1993a, b). Three research memoranda undertaken in the demographic analysis program over 1990-1991 are relevant: Project *D2: Preliminary Estimates of Undocumented Residents in 1990* (Woodrow 1991a); *Project D5: Preliminary Estimates of Emigration Component* (Woodrow 1991b), *Project D7: Uncertainty Measures for Other Components* (Robinson, Woodrow, and Ahmed 1991). For the census evaluation, the emphasis was on measuring overall undercoverage of all residents by age, sex, and race. Partitioning of legally resident and unauthorized or undocumented populations was not necessary and Woodrow (1991a) noted that the unauthorized or undocumented component might include some legally resident immigrants.[14]

Net Immigration by Authorization Status

Authorized Residents

In Robinson et al.'s (1993) analysis of 1990 census coverage, the implicit estimate for legal foreign-born residents as of Census Day 1990 would be 16.7 million as a minimum after incrementing the November 1989 estimate of

Woodrow (1991a, 1992c) with 250,000 additional legal immigrants over December 1989-March 1990 as described in Woodrow (1992b) and Woodrow-Lafield (1995a). That figure would have included at least 3 million Mexico-born authorized residents. For the "entered since 1960" population, the overall figure would be at least 13.4 million.

A prime source of uncertainty about the legally resident foreign-born population for 1990 is the size of the resident population having benefited from the agricultural legalization provisions of IRCA. With assumptions about resident agricultural legalization beneficiaries, the overall estimate could increase to 17.6 million and the Mexico estimate would increase rather markedly to 3.8 million. The component for authorized immigration over the 1980s was bounded by 5.9 and 8.3 million for modeling uncertainty in the total resident estimate (Robinson et al. 1991, 1993; Robinson, Woodrow, and Ahmed 1991), to account for uncertainties as to agricultural legalization and emigration.

The two published estimates for legally resident foreign-born persons in 1990 shown in Table 1 and for the Mexico-born portion shown in Table 2 are similar in methodological divergence from pre-1990 census studies. Citing nonspecific authorized immigration, including agricultural legalization beneficiaries, nonimmigrants becoming permanent residents in the 1990s, special EVD and TPF statuses, and dependents of IRCA-legalized beneficiaries,[15] Woodrow-Lafield (1995a) used estimates of 14.354 million and 17.690 million for the legally resident foreign-born population entered since 1960 and entered in all time periods. Clark et al. (1994) similarly allowed explicit amounts for agricultural legalization beneficiaries' presence, foreign students, and other nonimmigrants for overall estimates of 17.749 million, including 3.469 million Mexicans for 1990.

Unauthorized or Undocumented Residents

The Census Bureau's estimate is there were *3.3 million unauthorized or undocumented residents on April 1, 1990* as of a 1991 report. This figure was initially presented as a preliminary estimate (Woodrow 1991a) and underwent extensive review by internal committees, external demographers (Himes and Clogg 1992), and the Special Advisory Committee on Adjustment. Two approaches were used. The first one explored effects of differential coverage between the estimate of the unauthorized or undocumented population as of November 1989 based on Current Population Survey (CPS) data and the 1990 census. The second presented assumptions about total unauthorized or undocumented residents as of 1980 (2 to 4 million), total net unauthorized or undocumented immigration for 1980-1990 (2 to 3 million or 200,000 to 300,000 annually), and total IRCA legalizations for 1980-1990 (2 to 3 million). The assumption about net population change due to

unauthorized or undocumented immigration is grounded in studies of unauthorized or undocumented migration through the 1980s (e.g., Woodrow 1992c).

These direct and implicit estimates of the total number of unauthorized or undocumented residents as of April 1, 1990 converged on *a "point" estimate of 3.3 million as the best "working" estimate* as of a 1991 report. *The "likely" range associated with this point" estimate was given as 1.9 million to 4.5 million*, especially to account for the agricultural legalization. To account for the broad band of uncertainty of the unauthorized or undocumented component, the preliminary estimates of 1990 census coverage from demographic analysis assumed that *the true number of unauthorized or undocumented residents in 1990 was between 1.7 million and 5.5 million* as a worst case scenario of census undercoverage (Woodrow 1991a, Robinson et al. 1991, 1993). These "bet the house" limits (Das Gupta and Robinson 1991) represent the 99.9% limits and the 95% limits for the unauthorized or undocumented component are *2.4 million to 4.7 million*. In its review, the U.S. General Accounting Office (1993) did not recognize this difference and implied the Census Bureau had an unrealistically high upper limit on the number of unauthorized or undocumented residents in 1990.

This preliminary point estimate for net unauthorized or undocumented immigration for the 1980s and associated ranges gained legitimability as the Census Bureau's official work on the component. A subsequent report (Fernandez and Robinson 1994) extrapolated the point estimate of 3.3 million simplistically to October 1992 and April 1994 as a conservative upper limit with INS estimates for unauthorized residents as a lower limit (Warren 1993).[16]

Coverage and Components Errors

Census Coverage of Resident and Legally Resident Foreign Born

A comparison of the legally resident foreign-born population estimate with a census or survey estimate of foreign-born persons yields only a minimum for unauthorized or undocumented residents included in the census or survey, because there may be undercoverage of legal residents. Undercoverage of unauthorized or undocumented residents contributes to underestimation of unauthorized or undocumented residents in the United States (Woodrow-Lafield 1995a).

Demographic analysis estimates for the total 1990 resident population were detailed by age, sex, and race. This demographic detail for the net unauthorized or undocumented immigration component was synthetically estimated on the basis of the age-sex-country compositions of the generally legalized and agriculturally legalized populations. Census coverage research focuses on selected demographic and social characteristics (age, sex, race, Hispanic origin, area of residence, et al.)

without considering nativity status. The demographic analysis program offers limited view of Hispanic undercoverage so one might wonder whether the postenumeration survey estimates of Hispanic undercoverage might be representative of the absolute upper limit on undercoverage of Hispanic unauthorized residents. The key problem is that the postenumeration survey suffers from correlation biases, in a tendency to miss many of the same difficult-to-enumerate subgroups as the census. The composition of Hispanic undercoverage is unknown as to the reference groups of natives, lawful foreign-born residents, and unauthorized residents. Woodrow-Lafield (Forthcoming) allowed for up to 14 percent undercoverage of the foreign-born population, or as much as three million, which would mean that nearly two of every missed three persons could be foreign-born.

Plausibility Ranges for Total, Mexico-born

Based on detailed review (Woodrow-Lafield, Forthcoming) of possible errors in estimating unauthorized or undocumented residents for 1990, the greatest possible estimate would be about 8 million. That improbable extreme could hold only if all of the errors were in the direction of underestimating unauthorized or undocumented residents. A range of *2 to 6 million is defensible as reasonably representing the unauthorized or undocumented population in 1990* corresponding with a 95-percent level of certainty and liberal or broad assumptions of the ranges of possible errors. *The broader the range given for a particular estimated unauthorized or undocumented or legally resident population, the more conservative the statement about the population. A more narrowly specified range requires stronger support for the associated assumptions.*

Similarly looking at the evidence of total and authorized immigration from Mexico, *the number of unauthorized or undocumented Mexican residents as of 1990 is slightly under 1 million to slightly more than 2 million* (at 95-percent certainty) (Woodrow-Lafield 1996e). The likely range around a point estimate of 3.2 million for the legally resident Mexico-born population is 3 million to 3.9 million. The greatest possible unauthorized or undocumented estimate would be 2.7 million if all of the errors accumulated in the direction to minimize the legally resident estimate and maximize the unauthorized or undocumented residual.

Statistical significance testing and derived confidence intervals on point estimates can only be approximate with these types of authorized status population estimates. It is very critical to remember the underlying rationale of statistical inference, that as one broadens the confidence interval or raises the level of certainty associated with the interval, one decreases the chances of not including the true population parameter in the sample. If one were willing to accept only a 65% level of certainty, one could draw from Woodrow-Lafield's study (1996e) to state that

the total number of unauthorized or undocumented Mexican residents for 1990 ranged *between 1.2 and 1.9 million, a substantially narrower range.* However, there is considerable risk that the true population size lies beyond this range.

Beyond 1990

Authorized Immigration

Lawful Permanent Resident Alien Admissions

Since the 1990 census, there have been over 5 million admissions of lawful permanent residents, net of IRCA legalizations. That figure includes about one-half million from Mexico. Nearly two-thirds of the lawful permanent resident admissions in Fiscal Years 1990 and 1991 were legalization adjustments. The fiscal year 1991 was the peak year for agricultural legalization adjustments, primarily of the agricultural legalization-default beneficiaries. Many of the aliens, who applied for adjustment in fiscal year 1995, the first year of implementation of the new on-soil policy, did not gain permanent resident status until fiscal year 1996.[17]

Net Authorized Immigration

Alternative Series, Varying Emigrants, Agricultural Legalization Beneficiaries as Residents, or other Nonspecific

Alternative series of estimates for net authorized immigration[18] as of 1990 and beyond 1990 are presented in Table 5 that consider uncertainties as to emigration of authorized immigrants, incorporation of agricultural legalization beneficiaries as U.S. resident, and nonspecific sources of net authorized immigration. The range for the low (95,000), moderate (133,000), and extreme (195,000) assumptions about annual levels of emigration is narrow, although those differences would accumulate over the number of years. For the Mexico-born, these assumed amounts of emigration are slight given the emphasis on emigration of lawful permanent residents—9,000, 13,000, or 20,000 in accordance with Warren and Passel (1987b). The range for incorporation of agricultural legalization beneficiaries as residents is difficult to say and so to be viewed as tentative. The assumed amounts for incorporation of agricultural legalization beneficiaries as residents is 300,000 (250,000 for Mexico), 550,000 (400,000 for Mexico), or 850,000 (700,000 for Mexico). The range for nonspecific sources of legal immigration may be conservatively stated for all countries and yet may be well designed for Mexico. The assumed amounts for other nonspecific sources of authorized immigration are zero, 700,000 (250,000 for Mexico), or 1,000,000

Table 4

Lawful Permanent Residents Admitted to the United States, Fiscal Years 1990–1996

			All IRCA Legalizations					
	Total Admitted		(From 1982 and Agricultural)		IRCA SAW Legalizations		IRCA dependents	
Fiscal Year	Total	Mexico-born	Total	Mexico-born	Total	Mexico-born	Total	Mexico-born
1990	1,536,483	679,068	880,372	622,519	56,668	51,187	(X)	(X)

Source: 1990-1995 Statistical Yearbooks. Materials prepared for Binational Study (June 1995), Table 6. Immigrants Admitted by Major Category of Admission and Region and Selected Country of Birth: Fiscal Year 1996, (http://www.ins.usdoj.gov/public/stats/1007.html). U.S. Immigration and Naturalization Service.

(800,000 for Mexico). The latter set of assumptions is intended to encompass those residents whose status might be considered as neither authorized nor unauthorized or undocumented at the present time who might be sponsored by a naturalizing relative who is an IRCA legalization beneficiary. In a sense, this nonspecific component is an effort to make the accounting less atomistic or individualistic and to account for clustering or family patterns of migration resulting from IRCA. An expert's assumptions are only that subject to review of prior studies and possibilities for errors. The assumptions shown involve a certain degree of arbitrariness as to magnitude and composition.

The columns for net authorized immigration for entry 1960-1990 are based on carrying forward the estimated legally resident foreign-born population of Woodrow (1991a, 1992c) from December 1, 1989 to April 1, 1990 primarily with additional legal admissions and additional general legalizations for most tiers. Figures for net authorized immigration for 1960-1996 are constructed by surviving the 1989 base estimate until 1996, adding surviving numbers of admissions of lawful permanent residents 1990-1996 (net of legalization adjustments), adding generally legalized immigrants, subtracting estimated emigrants, adding agriculturally legalized immigrants, and adding other nonspecific amounts as indicated.

The first tier of estimates ((1) through (3)) for the legally resident foreign-born population or net authorized immigration as of 1990 or 1996 is most consistent with official procedures for counting individuals as contributing to the resident population as immigrants or settlers. This set is the lowest representation of net authorized immigration. The second tier of estimates ((4) through (6)) is slightly higher to reflect a low allowance for agriculturally legalized residents. With set (5), the estimate is about the same as for Clark et al. (1994). Among all the estimates, including the other tiers, sets (7) through (30), the amount of net authorized immigration as of 1990 ranged between 13,092,000 (3) and 15,854,000 (28). The amount of net authorized immigration from Mexico as of 1990 ranged between 3,199,000 (3) and 4,807,000 (28).

Net authorized immigration from all countries over 1960-1996 shows an increase of at least three million relative to the period 1960-1990, when holding assumptions constant. The low estimate appears in set (3)—16,105,000—and the high estimate in set (28) is 19,415,000. Net authorized immigration of Mexicans as of 1996 ranged from 3,870,000 (3) to 5,543,000 (28). The extreme allowance for nonspecific sources of authorized immigration may be beyond the range of reality, so that these upper limits might be shifted downward to set (20)—18,534,000 for all countries and 4,924,000 for Mexico. Dramatically higher figures are also conceivable as borne out by the earlier discussions. Depending upon the degree to which one of the alternative series might be more accurate than set (17), the divergence from prior estimation strategies would be greater or lesser. Fiscal years

Table 5

Net Legal Immigration, 1990 and 1996, Alternative Series, Varying Assumptions on Specificity, Residence of Agricultural Legalization Beneficiaries, and Emigration (Population in Thousands)

Description and Assumptions	Total Entered 1960-1990	Mexico-born Entered Before 1990	Total Entered 1960-1996	Mexico-born Entered Before 1996
With low-zero allowance for nonspecific,

Note: See text for explanation of various assumptions and other details of these calculations.

1996 and 1997 have been years of significant naturalization activities, especially among legalization beneficiaries, portending a "hump" in legal immigration. That echo of the amnesty could easily make estimates for legal status populations as of 1995 obsolete to experts, though highly visible among the outer circle.

Discussion, Policy, and Conclusions

Summary of Findings

To summarize, the upward trend in authorized immigration to the United States and, for Mexico, the focused impact of IRCA's amnesty programs, account for a gradually increasing presence of legally resident immigrants since 1980. The precise magnitude is difficult to pinpoint because the extent of U.S. residence among agriculturally legalized individuals, the volume of transitions from unauthorized or undocumented status into lawful permanent residence among family members of legalized immigrants, and timely accounting of nonimmigrants in the United States are not yet known. Ways of improving estimation for legally resident foreign-born populations are obvious, but few of the statistical improvements recommended by the National Academy of Sciences in 1985 (Levine, Hill, and Warren 1985) have been accomplished. The quantity of net authorized migration is more conservatively estimated with traditional definitions of permanent migration, tending toward overestimation of the quantity of unauthorized or undocumented migration, than with less restrictive definitions with inferences from multiple data sources.

This study has taken the direction of organizing the task of estimating legal status populations in a fashion more or less like production of official postcensal population estimates and projections (Keyfitz 1985). The uncertainties surrounding authorized and unauthorized estimates are great enough and the policy contingencies of sufficient merit that modeling strategies with multidimensionality are warranted. Point estimates tell a story about balance of authorized and unauthorized immigration over 1980-1996, but scholars should be careful in assigning credibility. The aim of presenting alternative series is not to obscure understanding of the demographic phenomena of net immigration by authorization status but, rather, to present coherent bases for long overdue statistical improvements in the monitoring of international migration to the United States.

A comparison of the 1990 census count for the foreign-born population with net authorized immigration series that allow for sources of uncertainty would yield unauthorized or undocumented residuals generally below the 3.3 million estimate for total unauthorized or undocumented residents. Series (2), (3), and (6) were close to it. It is conceivable the census data underrepresent the size of the foreign-born population in the United States, possibly by as many as one million persons

or more. Allowing for this unknown undercoverage would commensurately increase the unauthorized or undocumented residual. Even allowance for undercoverage of two percent would increase the unauthorized or undocumented estimate for 1990 by 400,000, but the increase might easily be one million or more.

A similar comparison of net authorized immigration estimates as of 1996 with foreign-born survey estimates suggests the *unauthorized or undocumented resident population in mid-decade may be scarcely higher than the estimates for 1990*. At first, this seems remarkable because the post-1990 CPS estimates are based on weighting strategies intended to compensate for undercoverage error in the 1990 census. Given post-1990 lawful admissions of 5 million to 6 million, the estimates for the foreign-born population from the CPS's in March 1994 (22.6 million), March 1995 (23.0 million), and March 1996 (24.6 million) seem scarcely higher than the 1990 census count of 19.8 million within which only about 615,000 had been incorporated for undercoverage (one-sixth of the estimated net undercoverage from postenumeration studies or one-eighth of that estimated from demographic analysis) (Robinson and Hansen 1996; Robinson et al. 1991, 1993). (Also see Waite 1995.) Depending upon which alternative series is most suited to realities in 1990 and 1996, there may not have been any increase in net unauthorized or undocumented migration between 1990 and 1996. Additional allowance of undercoverage of the foreign-born would commensurately increase the unauthorized or undocumented estimate. *The amount of net unauthorized immigration could be the same for mid-decade as in 1990, but a marked decline pertains for most scenarios*. To the extent that one tends to agree with the hypothesis that all or most agricultural legalization beneficiaries have changed residence to the United States, even if not here initially, or to expect that substantial numbers of legalization dependents will obtain immigrant visas, unauthorized or undocumented estimate would be lower. *The case of Mexico is very remarkable, because an apparent increase in net unauthorized or undocumented immigration over 1990-1996 would prove to be temporal or spurious under reasonable assumptions for agricultural worker settlement, family settlement, and sponsorship of dependents for IRCA legalization beneficiaries*. That timetable will depend on bureaucratic processes and continuity of preference categories and immediate relatives provisions as well as individuals' decisionmaking.

Census Programs: Estimates and Projections

Estimates

Official postcensal population estimates use an allowance for net immigration that draws on INS official statistics for lawful immigration and incorporates an allowance for net population change due to undocumented immigration. The amount

for the 1980s was based on net undocumented migration for 1975-1980 as of 1980 (Warren and Passel 1987a; Passel 1985). Period-of-entry data are more suspect for the 1980s and 1990s with fluctuating flows due to period factors (oil boom and recession, amnesty, and peso devaluation), suggesting that stock to stock comparison is a better approach. Various studies monitored net population change from undocumented migration throughout the 1980s by comparisons, but demonstrable deviation was unlikely given the range of sampling variability. Even sizable differences between estimates, e.g., fairly high numeric shifts in the population living below the poverty threshold (greater than the foreign-born), may not be statistically significant and be interpretable only as indicating continuation of prior levels of poverty.

Measuring differences between population estimates based on different sources or changes in population subgroups with national surveys, whether the long-form sample survey in the decennial census or the Current Population Survey, relies on comparability of measurements with similar questions, sampling, weighting procedures, and nonsampling errors. Post-1992 CPS estimates for the foreign-born population are not entirely comparable with earlier foreign-born estimates from various CPS's for three reasons. First, the 1993 CPS estimates are the first ones based on the 1990 census population rather than the 1980 census population. Second, revisions to the methodology for production of independent population controls included adjustment for 1990 census undercoverage by age, sex, race, and Hispanic origin (Woodrow-Lafield and Short 1995). This might insufficiently allow for undercoverage of the foreign-born population because differential nativity risks of omission were neither measured nor adjusted. Demographic analysis estimated 1990 census undercoverage at 4.8 million, but the PES undercoverage adjustment of 4.0 million was incorporated into the CPS weighting procedures. Third, CPS coverage may be better for the Mexico-born population in the 1990s than previously due to greater trade and business opportunities and inclusion in the CPS of working, sojourning Mexicans not in the legally resident estimate.

Projections

The Census Bureau population projections program makes low, medium, and high level assumptions about net migration, for which international migration dominates native migration. These assumptions have changed greatly over the past ten years to become more commensurate with changing immigration levels (Ahlburg and Vaupel 1990). The current series assume that net immigration ranges between 300,000 and 1,370,000 annually (U.S. Bureau of the Census 1993c). That range allows for a range of about 280,000 to 1,020,000 for net authorized immigration

and a range of 100,000 to 300,000 for net unauthorized or undocumented immigration. (See Woodrow 1992a and Day 1992.) A very relevant point is that the allowances for population change are incorporated irrespective of nativity or authorization status.

INS Programs: Multiple Missions

Unauthorized Immigration Estimates

The major methodology for deriving legal status estimates is one that first aggregates an estimate of the legally resident foreign-born population from a myriad of INS data sources and demographic techniques. A second step uses this to disaggregate an estimate of the whole foreign-born population from the census or Current Population Surveys of the U.S. Bureau of the Census to find the unauthorized or undocumented portion. Net error affects the unauthorized or undocumented estimate.

INS official estimates for unauthorized residents are derived with another methodology without deriving the counterpart of legally resident foreign-born population. These estimates for October 1992, October 1994, and October 1996 are constructed with various components for unauthorized or undocumented population subgroups: those resident since before January 1, 1982 who did not legalize under IRCA by 1988, net nonimmigrant overstays after 1988, and net unauthorized or undocumented migration by border-crossers after 1988. The technical discussion of the underlying methodology is detailed in one report (Warren 1994a), but the most recent report includes only a sketchy description of the methodology and assumptions (U.S. Immigration and Naturalization Service 1997a). The first of these components is rather small. The second component is based on failures to depart among nonimmigrant arrivals within specified periods. A major problem with this component's estimation is the right-censoring of nonimmigrant cohorts currently present in the United States. The third component is predicated in part on the Census Bureau's allowance for net population change due to unauthorized or undocumented migration, residual studies of Mexican unauthorized or undocumented migration before IRCA, presumed efficacy of IRCA border controls, and unmeasured Mexican unauthorized or undocumented migration.

One of the reports from INS (Warren 1994a) includes a table reference to a total resident undocumented population in 1990 of 2.6 million. The figure is not based on empirical examination for 1990, but, on the contrary, this figure stems from simple extrapolation of the October 1992 estimate (3.4 million) (Warren 1993, 1994a) by assuming net unauthorized immigration of 300,000 annually

for 2.5 years. If the total number of foreign-born persons in 1990 had been 20.4 million (as in Robinson and Hansen 1996), then this INS figure would imply 17.8 million legally resident foreign-born persons, about the same as argued by Woodrow-Lafield (1995a). This scenario would mean that foreign-born residents would have to have had equal coverage to the overall population which seems very unlikely (Woodrow-Lafield 1995a: 200). If undercoverage greater than .6 million were allowed, such as 1.0 million, then the estimated number of authorized residents would be constrained to increase to 18.2 million to maintain the unauthorized or undocumented figure of 2.6 million. Having performed this exercise, the latest release (U.S. Immigration and Naturalization Service 1997a) showed an increased figure, 3.9 million, for October 1992. Working backward, the extrapolated figure for 30 months previously would be *3.3 million*! Both the U.S. Bureau of the Census and the Immigration and Naturalization Service have "authenticated" the point estimate.

Taking Robinson and Hansen's (1996) figure of 20.4 million for foreign-born in 1990,[19] and Fernandez and Robinson's (1994) continued acceptance of the estimate of 3.3 million unauthorized or undocumented residents for 1990, the implied figure for the legally resident foreign-born population for 1990 would be 17.1 million. The Fernandez and Robinson (1994) extrapolated range for 1994—3.5 to 4.0 million unauthorized or undocumented residents—implies a legally resident foreign-born population of 18.6 million to 19.1 million in March 1994.

Enforcement Evaluation

Methodological work would be helpful for evaluating the efficacy of INS border enforcement strategies in the 1990s. Official INS estimates for unauthorized residents do not fulfill that purpose because net annual entries without inspection are assumed. Distinguishing between measures for net population change due to undocumented immigration and net undocumented immigration is essential for evaluating border enforcement, interior detection, and work site enforcement strategies. The Census Bureau has an established orientation toward the former type of measure, as appropriate for its mission of statistically describing the population without regard to legal status characteristics. Therefore, post-arrival transitions from unauthorized to authorized status, as possible through either a wide-scale amnesty program or individual eligibility, is of no consequence for measuring overall population change. The time frame is generally long as well, such as a decade. The INS enforcement evaluation requires more immediate and focused measures of net undocumented immigration in a highly politicized budgetary process.

Methodological work is also needed for nonimmigrant overstay research and to assess relative priorities of the agency for border enforcement and interior detection strategies. The sheer volume of nonimmigrant arrivals in the United States mandates a closer look by demographers. In 1986 the Visa Waiver Pilot Program was established to permit certain nonimmigrant visitors (for stays not to exceed 90 days) from specified countries to enter on a temporary basis without nonimmigrant visas. As of fiscal year 1994 there were 22 countries whose citizens were eligible under the program after expansion and extension of the initial pilot program (including countries with reciprocal waivers to U.S. citizens and other countries assumed unlikely to contribute visa overstays). Since the advent of the program, the integrity of the NIIS for monitoring nonimmigrant visa patterns, e.g., stays and overstays, has deteriorated which is regrettable given great promise of the NIIS (U.S. General Accounting Office 1988; Woodrow 1987).

Benefits Provision

Naturalization is regarded as a benefit among the various INS activities and processing services. In the past, the agency burden from applications for naturalization was small, but the process was still beset with bureaucratic delays and pitfalls (North 1987). Efforts reduced these difficulties in the early 1990s, but the transition to eligibility of IRCA-legalized population with an anticipated burden upon the naturalization benefits arm of the agency. As of April 1996, nearly 6 million immigrants may have been eligible to apply for U.S. citizenship, according to one estimate (U.S. Immigration and Naturalization Service 1996c). Young immigrants, maybe another 10-15 percent, would perhaps be eligible to derive citizenship upon a parent's naturalization. A total of 10.5 million would be eligible to apply over 1996-2000.

Naturalization levels in the late 1990s appear likely to exceed or equal admissions of legal permanent residents. If INS (and other federal agencies) manages to resolve the problems that have created the naturalizations backlog, then both the lawful permanent resident population and aliens eligible to apply for naturalization could decline from the 1996 levels.

Systematic Research Program

Systematic collection of national survey data on the population by nativity, country of birth, parents' country of birth, citizenship, and period of entry is a major step toward systematically monitoring net immigration to the United States by authorized status. Allied programs for insuring accuracy of these survey results should be sustained and nourished within the federal statistical community. This

task is pervasive across the decennial census adjustment issue, 2000 census design, inter-censal population estimates, and measuring net population change due to unknown or unauthorized immigration.

The essential companion effort is systematic utilization of INS data sources on authorized immigration and temporary authorization for entry to the United States. This effort must incorporate procedures for tracking those who have come into the United States to ascertain return migration levels and produce population measures. Finally, any proposed legislation affecting individuals' legal status may have far reaching consequences for which consultation with immigration demographers is critical.

Data Recommendations

This study has organized the task of estimating legal status populations in a fashion more or less like the production of official postcensal population estimates and projections. The aims of presenting alternative series are to cover plausible scenarios in recognition of uncertainty, identify scenarios as proximal to the true scenario through iterative logic, and present coherent bases for statistical improvements in monitoring international migration by legal status to the United States. Consensus about net authorized immigration is critical for consensus about net unauthorized or undocumented migration for which social scientists and policymakers continually renew discussions. The estimated quantity of authorized migration is more conservative with traditional definitions of long-term migration, tending toward overestimation of the quantity of unauthorized or undocumented migration, which would be provocative for national and foreign policy.

Statistical monitoring of international migration to the United States has problems intrinsic to the data sources and the phenomena (Willekens 1994). Expert judgment is at the core of this field of demographic research and might play a bigger role than technical demographic expertise. Yet the modeling prospects are excellent for those capable of merging expert judgment with sophisticated modeling of error distributions for various components of authorized and unauthorized or undocumented immigration. As discussed above, even the worst case scenarios have rather delimited ranges as to numbers of net authorized immigrants and net unauthorized or undocumented immigrants (Woodrow-Lafield Forthcoming).

The preeminent recommendation is the establishment of a comprehensive infrastructure with the mission of measuring all aspects of international migration. Six data collection and analysis programs are vital for the statistical foundations of understanding U.S. immigration: (1) studies of demographic impacts of the agricultural legalization; (2) continued surveys of generally legalized immigrants,

(3) innovative surveys on composition of the foreign-born population by type of status; (4) transition-oriented modeling in measuring net immigration by legal status; (5) special surveys of relatives living abroad who emigrated from the United States; and (6) studies of survey and census coverage of the foreign-born.

First, the significance of the agricultural legalization for immigration policy warrants social science research on its consequences. To address net change from undocumented migration, demographers need to know the settlement and family migration consequences stemming from those IRCA provisions. The proportion of unauthorized workers within the agricultural workforce is increasing in the 1990s, as the proportion legalized under IRCA declined. Agricultural workers may have moved into other labor force sectors or may have returned to their native countries.

Second, continued surveys of the generally legalized immigrants would track their experiences of naturalization, family unification, and assimilation into American society. These surveys were discontinued after the 1992 wave, but the data effort is unique as a longitudinal undertaking.

Third, a special survey to measure the foreign-born population's composition on legal status may be propitious to identify the heterogeneity of the lawfully present population of foreign birth. Without a legislative mandate, such a survey would be unlikely under data collection programs.

Fourth, better ways of modeling transitions among legal statuses for migrants must be devised in studying migration in the modern world. Existing administrative records databases are a gold mine of information about individuals but the focus is blurred by incompatibilities of data systems and insufficient resources. Cross-sectional perspectives risk biased perceptions of a dynamic phenomenon. The statistical emphasis is on discrete events of arrival and departure as opposed to durations of stay, leaving a considerable gap in knowledge of the convergence of temporary residence with permanent residence.

Fifth, multiplicity surveys of relatives living abroad are recommended to monitor levels of return migration by comparison with earlier surveys over 1987-1988. That slight upturn in return migration to Mexico might have been the beginning of a new trend. Such a survey has added value in its measures, albeit crude, of the magnitude of family unification since IRCA.

Sixth, studies of survey and census coverage of the foreign-born population are relevant for measuring unauthorized immigration whether or not there are comparable survey data on individuals' legal status, as suggested above. Indirect estimation methodologies are biased by undercoverage of the foreign-born population. Consequently, benchmarks for authorized and unauthorized immigration confound coverage and classification errors. As the Hispanic population becomes the largest minority population, accuracy in population figures merits emphasis.

Notes

1. Nor does the INS include these records in the micro data files provided to the Census Bureau for its population programs.

2. That file has not been regularly updated and does not completely cover "approval" processing.

3. Certain aliens holding EVD status from Afghanistan, Ethiopia, Poland, and Uganda, who had resided here since July 1, 1984, were eligible to adjust to temporary and then to permanent residence status under the legalization program.

4. Figures cited were as high as 73,000 students and 250,000 visiting nationals (*Interpreter Releases* 55,645-7, June 19, 1989).

5. An indirect indication of this possibility is that the estimate for the legally resident foreign-born population in Texas in 1980 (Passel and Woodrow 1984b) yielded an unauthorized or undocumented residual that was much lower than the population legalized after long-term residence.

6. Research on residual measures for net unauthorized or undocumented migration has not kept pace with collection of nativity data in Current Population Surveys in June 1991, March 1994, March 1995, and March 1996.

7. This is largely based on reported date of last entry to stay in the United States.

8. The size of this cohort may exceed the actual number of persons arriving as nonimmigrants because an individual may enter and exit more than one time.

9. The datum is date of current nonimmigrant class admission. Therefore these statistics and, presumably those of Kraly and Warren, may actually include earlier entrants.

10. These adjustments are as published in INS yearbooks.

11. The proportions were calculated on the basis of calculations for 90 individual countries.

12. Although the response categories were very detailed, these were years during which individual SAW applicants' statuses changed from applicant to temporary residence, to permanent residence, or to denied applicant.

13. Espenshade (1995) apparently did not reconsider this difference, but he may have been misled by Fernandez and Robinson's (1994) failure to distinguish the multiple assumptions for making the initial estimate of 3.3 million.

14. As mentioned previously, postcensal population estimates and projections require only measures of population change rather than time-specific designations of legal and unauthorized or undocumented status. This research may not be useful for evaluating enforcement efficacy.

15. Woodrow-Lafield (1994b, Forthcoming) also incorporated amounts for more nonspecific legal immigration.

16. The discussion discusses the 3.3 figure in the context of INS official estimates.

17. In a sense, this new policy may have contributed to the appearance of a downward shift in legal immigration for 1995 relative to earlier years that some interpreted as real.

18. These tables were developed with published tabulations (U.S. Immigration and Naturalization Service 1991, 1992b, 1993, 1994, 1995, 1996a, 1997b). The technical demography of estimating the population by legal status depends more critically on coverage issues and classification issues than on these simple tasks. These results might differ slightly from official counting of immigrants in official postcensal population estimates.

19. This figure is based on illustrative calculations but the authors did not explain whether the calculations were done using an adjustment matrix used for the CPS weighting scheme (Cohany, Polivka and Rothgeb 1994) or with findings from demographic analysis of 1990 census coverage. The CPS still has undercoverage relative to the independent population controls (Waite 1995).

Quantification of Migration

Viewing Emigration at Century's End

Karen A. Woodrow-Lafield

Introduction

For most of U.S. history, net immigration, the "residue" of immigration, has represented an important source of population growth, accounting for 30 percent or more over three decades and possibly for a fourth as well (Gibson 1975, 1992). In the broadest sense accounting for generational impacts, fully 31.8 percent of the population in 1990 would be attributable to net immigration that occurred during the period 1790-1900. Only 19.3 percent of the current population would be attributable to the more recent net immigration since 1900. This is particularly notable as 1900-1910 is often considered the historically high decade (Gibson 1992).

Emigration[1] has had a substantial role in offsetting immigration flows in both the short-run and long-run, from "high" immigration decades such as 1900-10 to "low" ones such as 1930-40. "Immigration" and "net immigration" are not equivalent as, historically, about one-third of legal immigrants for 1900-1980 had emigrated as of 1980 (Warren and Kraly 1985). That ratio is based on several studies reviewed below. Pointing to its significance, Keely and Kraly (1978) noted that population modelers would conventionally assume emigration as either equaling "10 percent

of alien immigration" (Zero Population Growth 1977) or implicitly set to zero (U.S. Bureau of the Census 1975).

There has been a lesser administrative focus on emigrants than on immigrants for the United States. INS collected partial information from departing alien emigrants only from 1907 to 1957. Direct measures are generally not possible or feasible as the nature of the U.S. border and magnitude of population movements would preclude comprehensive collection of statistics. Other countries' data on immigrant admissions or enumerated populations by birthplace are generally inadequate for measuring emigration because non U.S.-born persons have dominated the emigration flows.

From Nil to Noticeable: Trends in Emigration

Estimates of emigration are important for the Census Bureau's programs of population estimates and projections, including coverage evaluation of the decennial census and national surveys (Fay, Passel, and Robinson 1988; Himes and Clogg 1992). Indirect measurements of emigration have been devised according to the changing nature of immigration and official statistics. In assessing future levels of legal immigration, the U.S. General Accounting Office (1988:4) noted there is "no comprehensive approach to counting emigrants." For the 1960s and 1970s decades, emigration levels were assessed with two main analytic approaches that decomposed changes over time, either in the foreign-born population or in the legally resident foreign-born populations to legal immigration, mortality, and variation in coverage, yielding emigration as a residual. Each found higher emigration levels than for the 1940s and 1950s, suggesting that return migration was rising as legal immigration levels rose.

Emigration over 1960-1970

The first approach, by Warren and Peck (1980), derived an estimate of 1.1 million for foreign- born emigration between the 1960 and 1970 censuses by looking at change in the foreign-born population due to legal immigration, estimated mortality, and census coverage. This useful method of intercensal comparison was recognized as inappropriate for subsequent periods, as noted in Himes and Clogg (1992), when inclusion of a substantial number of undocumented residents creates another major unknown—net undocumented migration.

Emigration over 1970-1980

The second approach is best described as iterative, to first estimate emigration for the 1970s, and second, to estimate net undocumented migration as of 1980.

Warren and Passel's (1987a) efforts focussed on specifying components of change to the legally resident alien population, with modeling based on the time series of INS Alien Address Registration data for 1965-1980. Relative to more than 3.9 million legal immigrants during the 1970s, an estimated 1.2 million emigrated. Among 614,000 from Mexico, some 120,000 emigrated (Warren and Passel 1987b). Jasso and Rosenzweig (1990:125-138) carried out a similar analysis finding higher "emigration losses," but differential coverage and mortality losses were included with emigration losses.[2] Indeed, their average annual loss of 157,000 exceeded Warren and Passel's estimate by one-third. This time series modeling could not be extended to measure emigration during the 1980s and 1990s, because the INS no longer registered legally resident aliens annually.

The level of emigration during the 1960s and 1970s was certainly higher than allowed in official population estimates for the 1970s and early 1980s—only 9,000 foreign-born emigrants annually. To the extent that actual emigration was higher, as evident from these analyses, the discrepancy served to offset the omission of net undocumented migration. Upon completion of Warren and Passel's (1987a, b) dual analyses of emigration and net undocumented migration, annual allowances of 133,000 foreign-born emigrants and 200,000 as population change due to net undocumented migration were established for constructing census-level postcensal population estimates (Passel 1985, 1986).

Some of these studies adopted entry cohorts, defined broadly as entered in the most recent ten years or earlier, as reference populations, given the analytic value of tracking over adjacent censuses. Others adopted broad time intervals for analysis. There is a substantive interpretation also, because immigrants settled here for ten years or more seem more likely to remain than immigrants of lesser durations or, to rephrase, more recent entrants are more likely to include short-term stayers. The Immigration and Nationality Act recognizes five years of residence as denoting commitment necessary to become a naturalized citizen. Attrition through emigration is probably occurring throughout time and the life cycle so that emigration measures suffer from right-censoring.

Over 1940-1980, emigration levels seemed to be increasing as immigration levels were also increasing, following the decline of mid-20th century. Further corroboration of this is found with Borjas and Bratsberg's study showing that emigration for immigrants entering in the 1970s as of 1980 may have amounted to 900,000, which equaled three-quarters of that for all period of entry groups in Warren and Passel (1987b). The crucial question is whether the level found for 1960-1980 is sufficiently descriptive of emigration levels for 1960-1990 and 1960-1999 or whether emigration has perpetually increased in the latter half of the 20th century as the foreign-born population increased dramatically.

Recent Emigration

Emigration levels for 1960-1990 and 1960-1999 might be similar to levels over 1960-1980. This might be so if either the propensity to emigrate is lower among contemporary residents than among prior cohorts or origin or other characteristics associated with lower propensity to emigrate are more highly represented among the foreign-born recently residing in the United States. The compositional mix of the foreign-born population has shifted. First, the population includes greater proportions of (1) Latin Americans and Asians for whom emigration has seemed lower than for Europeans (Jasso and Rosenzweig 1990; Warren and Kraly 1985). Second, many immigrants entered under visa categories logically associated with lesser likelihood of return migrating, such as refugees, asylees, adjustees from nonimmigrant statuses, and formerly undocumented or temporarily resident individuals. Three studies are relevant for considering emigration levels for the 1980s—new empirical evidence, sensitivity analyses, and a resurrection of the intercensal approach.

Empirical Evidence of Emigration in the 1980s

First, superseding methods invalidated by data inadequacies or changing legal status of immigrants, the Census Bureau pioneered another data collection method to measure emigration in the 1980s (Woodrow-Lafield, 1996a and Woodrow, 1991c). These special questions on Current Population Surveys (CPS) (in 1987,1988, and 1989) about emigrant parents, children, and siblings of U.S. residents yielded baseline estimates for emigration lower than estimated historical levels.

However, the emigrant population represents a small population relative to the U.S. resident population. Multiplicity survey estimates of emigrants and Americans living abroad are subject to as many, or more, limitations as are other CPS estimates. Results based on a relatively small number of cases should be cautiously interpreted and small differences between estimates may not be significant after examining standard errors or considering nonsampling error (Waite 1995). Estimating emigration with surveys of residents has two limitations leading to underestimation— measuring recent emigrants in greater numbers than and, presumably, better than earlier emigrants and measuring only emigrants having U.S. relatives. A third limitation could involve overestimation—measuring emigrants without specificity as to former status (whether undocumented, nonresident aliens, or lawfully permanent resident). Given possible biases, Woodrow-Lafield (1996a) demonstrated that current emigration levels could equal or exceed emigration of the 1960s and 1970s (Warren and Peck 1980; Warren and Passel 1987b).

Emigration Component in 1990 Census Coverage

The 1990 census coverage evaluation (Robinson, Ahmed, Das Gupta, and Woodrow 1993) incorporated a preliminary estimate of emigration of legal residents during 1980-1990 (Woodrow 1991b) in combination with a preliminary net undocumented immigration component for 1980-1990 (Woodrow 1991a). Because emigration assumptions are involved in estimating legally resident immigrants, underestimation of emigration would lead to underestimation of undocumented residents. Overestimation of emigration would result in overestimation of undocumented residents.

In recognition of this confounding of emigration and net undocumented migration and the dearth of evidence that emigration levels had changed over 1980—1990 relative to previous decades, a conservative stance was adopted. The amount of the net emigration component for the legally resident foreign-born population for 1980—1990 was set at 1.3 million (for a total of 1.6 million including native-born).[3] Woodrow (1991b) stipulated that net emigration of foreign-born for the 1980s could vary between .8 million and 2.2 million (1.0 and 2.6 million in total). These limits were based on the multiplicity-based ranges from Woodrow-Lafield (1996a) and sensitivity analyses in Woodrow (1991c).

Some simulation results were based on using emigration rates by age, sex, and period of entry (Warren and Peck 1980), with multipliers of .5 and 1.5, and showed possible emigration of 1.3 million to 2.3 million for the 1980s. An alternative simulation using crude emigration rates for recent entrants by region of origin (Warren and Passel 1987b) showed an amount of 1.9 million. These amounts are not surprising, given the simplistic synthetic calculations and greater immigrants denominators for the 1980s relative to the 1960s. Immigration had nearly doubled.

Intercensal Analysis

After release of 1990 census data on the population by nativity, origin, and period of immigration, Ahmed and Robinson (1994) presented emigration estimates for 1980—1990 based on an intercensal analysis similar to Warren and Peck's (1980) for the 1960s. This methodology had been deemed less useful than Warren and Passel's (1987b) for analyzing foreign-born emigration in the 1970s due to the simultaneity of unknown legal emigration and net undocumented immigration and the necessity of measuring *legally resident foreign-born emigration*. In their revival of the intercensal approach, Ahmed and Robinson (1994) do not treat the problem of net undocumented immigration, i.e., of inclusion or coverage of undocumented residents.

Fortunately, the Ahmed-Robinson result falls within the range described previously.[4] One may be skeptical about heeding their assertion of higher emigration in the 1980s than in the 1970s. Apart from fundamental questions about applying the intercensal methodology in the context of continuing undocumented immigration, the findings are merely the consequence of an assumption that emigration in the 1980s occurs at about the same propensity for pre-1980 immigrants and post-1980 immigrants within age, sex, and country of birth subgroups. This amounts to "averaging" the propensity to emigrate across a great expanse of heterogeneity—social capital, human capital, socioeconomic assimilation, social networks, and favorability of origin communities. To quote from Vaupel and Goodwin (1987:728), "Populations are heterogeneous. Averages hide that heterogeneity."

A similar, simplistic application of crude emigration rates for legally registered aliens in 1980 who had entered in 1975-1980 with estimated authorized immigration for the 1980s and the 1980 population would scarcely be credible. As described above, Woodrow-Lafield (1991c) prepared such an emigration estimate for 1980—1990 drawing on Warren and Passel's work with detail for region of origin and period of entry. The overall result of 1.9 million emigrants may be useful for setting an upper boundary on emigration, but the assumptions create an anomaly. This simplistic model forces North America as the dominant region sending emigrants abroad, but it seems implausible that nearly 40 percent of lawful permanent residents admitted recently would emigrate or return to their origins.

Assumptions on Emigration for 1980-1990?

The preponderance of evidence about emigration is more adequate for positing a broad range than for stating that emigration levels are higher in the 1980s or 1990s than in the 1970s. Is holding this opinion an example of a tendency among demographers whom Preston (1993:595) has described as "unusually reluctant to commit Type II errors—saying that something is true when it isn't . . . and unusually prone to committing Type I errors-failing to say that something is true when it is?" In general, the Census Bureau's confidence in emigration estimates has been gauged by the commensurability of the allowance for net population change due to net undocumented migration. This is certainly indicative of the same caution while at the same time adapting to a layman's perception that rising immigration would be necessary and sufficient for higher emigration.

In positing estimates for net authorized immigration of the 1980s and 1990s, prior research is a guide for assumptions about the level and composition of emigration flows. Composition by age, sex, and period of entry can be based on Warren and Peck (1980), as used at the Census Bureau throughout the 1970s and 1980s for population estimates and projections and by census coverage researchers (Fay,

Passel, and Robinson 1988). Legal foreign-born emigrants can be distributed to country or region of origin based on the historical pattern of levels and rates of emigration described in the research literature (Warren and Kraly 1985), as also employed in undocumented estimation (Woodrow and Passel 1990; Woodrow 1992).

The Tide of Net Immigration from Mexico

Mexican migration to the United States is well known to consist of a huge volume of temporary migration relative to a lesser volume of permanent migration (Massey and Singer 1995; Espenshade 1990; Lowell 1992). In past and present cross-sectional analyses, the probable inclusion in the census of Mexican temporary migrants may complicate interpretations of losses due to emigration. Setting this problem aside, the Mexican population residing permanently in the United States, of both authorized and unauthorized or undocumented statuses, is the outcome of progressive levels of permanent immigration over the past four decades. The initial migration levels soared in the late 1970s, and that initial trip was likely to have led to additional trips and eventual settlement for a segment of those ever migrating (Donato, 1993, 1994; Donato, Durand, and Massey, 1992). The undocumented presence was partially legitimated with the legalization provisions of the Immigration Reform and Control Act of 1986. The Mexico-born population has increased dramatically over 1950 to mid-1990's, but that increase has been dominated by authorized immigration—primarily family-based and legalization-based.[5]

The current magnitude of the Mexico-born population poses conflicting expectations about return migration levels. In one sense, there might seem to be lesser propensity for return migration given a greater density on authorized status, greater demographic diversity, and possibly greater representation of sending communities at migration maturity. Alternatively, the Mexico-born population could be approaching a "critical mass" for return migration. That is, at some time, return migration could become more easily measurable or discernible, despite limitations of methodologies, simply because of its volume as a function of the larger size of immigrant cohorts over the 1970s, 1980s, and 1990s.

Allusions to the waves and tides of undocumented migration portray the variation in flows, as variation from one wave to another in magnitude. If one were to describe Mexican immigration in 1930-1950 as at low tide, then the 1980s and 1990s are ones of high tide. Most of the content in the volume returns, but some remains. The simile falls apart when considering the residue, because wave upon wave of immigration leads to an accumulation. This accumulated Mexican-born population is, however, subject to returning just as portions of preceding waves. To take an extraordinary scenario, would a notable fraction of Mexicans leave California,

Texas, Illinois, and Florida to return if there were to be a sustained boom of economic prosperity in Mexico?

Those with legal status may be less likely to emigrate (Lindstrom and Massey 1994). Legal status is often obtained after a lengthy time during which the sending community becomes more oriented to having members in the United States, the migrant becomes more assimilated, and the social network within the United States grows (Massey, Goldring, and Durand 1995). The stay becomes defined as permanent (Roberts 1995). Conditions in Mexico may be more favorable toward Mexicans deciding to stay in the United States, as remittances are recognized as valuable (Massey and Parrado 1994), the Mexican economy is struggling, and nationality rights for non-residents are now preserved. Among immigrants legalized after long-term undocumented residence, primarily from Mexico, socioeconomic measures correspond with strong sentiments toward naturalization, family unification, and remaining in the United States (Woodrow-Lafield 1995, 1996b).

Prospects for Measuring Emigration in the 21st Century

Emigration is conceptually dense and the task of measuring emigration from the United States has been and will continue to be challenging. This brief review and Kraly (1997) have demonstrated these points while reviewing prior research and the possible insights from forthcoming research. Whether such empirical analyses will be realized will depend on data creation and researchers' ingenuity. The long-awaited multiplicity surveys of emigration received funding primarily through 1990 census coverage evaluation programs, and prospects for a renewal of these surveys are unknown. The last data set in the series, in June 1991, has neither been analyzed nor released.[6]

Yet the greatest strength of these multiplicity surveys may be monitoring emigration levels for detecting gradual or sudden shifts. For example, Woodrow-Lafield (1996a) reported a significant increase in Mexico-born emigrants over the July 1987-June 1988 period. Border control and employer sanctions provisions of IRCA may have forced some undocumented aliens to return to Mexico, although a competing explanation is that newly legalized aliens may have chosen to visit their origin communities.

The statistical infrastructure within Mexico has the potential of yielding valuable data for the monitoring of population movements (Garcia y Griego 1985). U.S. sources are not at all pertinent to the inclusion of temporary migrants or their patterns of returning to Mexico (U.S. General Accounting Office 1993). Ethnographic surveys have given important indications of these flows through migration histories (Massey et al., 1987). The prospects for measuring flows from Mexico

into the United States may be poorer than the prospects for measuring the reverse flows, but the latter has considerable portent for interpreting the highly visible signs of border crossing and INS enforcement activities.

Notes

1. Throughout this discussion, emigration refers to only emigration of foreign-born persons. Some cited sources are relevant for native emigration. Foreign-born emigrants have consistently outnumbered native-born emigrants, for which estimates have been based on similar intercensal cohort analyses, analyses of Canadian census data for Americans (Finifter, 1973), and foreign census data for Americans (Fernandez, 1987).

2. Another study by Jasso and Rosenzweig (1982) traced the representation of legally admitted immigrants in 1971 in subsequent cross-sectional data to portray demographic characteristics of emigrants.

3. The age-sex-race distribution conformed with those for previous coverage evaluations that used work of (Warren and Peck 1980) for demographic characteristics of emigrants in the 1960s.

4. The population estimates methodology uses this allowance for foreign-born emigration, but this shift is almost wholly countered by an increase in the allowance for population change due to net undocumented immigration.

5. Woodrow (1992) shows this quite clearly, disaggregating the Mexico-born population to its legal and undocumented components.

6. The U.S. researchers, Frank D. Bean and Karen A. Woodrow-Lafield, sought access to these data without success.

Characteristics of Migrants

The Process of Acquiring Citizenship at Birth in Mexico and the United States

Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor & Paz Trigueros Legarreta

Citizenship at Birth—United States

At birth, according to U.S. nationality law, a person is either a national of the United States—a person owing permanent allegiance to the United States—or an alien. Most, but not all, nationals of the United States are also citizens of the United States. In general, citizenship may be acquired at birth or through naturalization. There are two main principles that nations use to confer citizenship at birth, *jus soli*—that is, citizenship based on place of birth, and *jus sanguinis*—that is, citizenship based on kinship. While some nations use one or the other principle, the United States follows both principles.

The principle of *jus soli*, a guiding principle of feudalism and of English common law, was codified in the Fourteenth Amendment to the Constitution (1868), which reads:

> All persons born or naturalized in the United States, and subject to the jurisdiction thereof are citizens of the United States and of the State wherein they reside.

As the Fourteenth Amendment makes clear, there are two requirements for acquisition of citizenship via *jus soli*: physical birth in the United States and birth subject to the jurisdiction of the United States. Thus, persons born in the United States to diplomatic personnel representing foreign countries do not acquire U.S. citizenship at birth, because diplomatic personnel are not subject to U.S. jurisdiction; and persons born on board foreign-flag ships in U.S. territorial waters do not acquire U.S. citizenship via *jus soli*. Federal legislation has extended citizenship at birth to persons born in most territories and possessions of the United States. For example, the Act of 1952 (66 Stat. 163) grants citizenship to persons born in the Virgin Islands after January 17, 1917, a date one week before the United States purchased the Virgin Islands from Denmark; on the other hand, persons born in the Philippines during the period when it was a Commonwealth of the United States (1898-1946) were nationals but not citizens of the United States.

Under the principle of *jus sanguinis*, the United States grants citizenship at birth to persons born abroad to two U.S. citizen parents and also to persons born abroad to one U.S. citizen parent (and an alien parent), provided that the U.S. citizen parent meets the requirements to transmit citizenship. These requirements—notably physical residence in the United States for a specified number of years during specified periods of the life course—have changed over the years, so that date of birth is a key factor in ascertaining the rules governing acquisition of citizenship at birth for particular individuals. For example, persons born between January 13,1941, and December 23,1952, are covered by provisions of the Nationality Act of 1940 (54 Stat. 1137), which stipulates that, in order to transmit citizenship, the U.S. citizen parent must have previously resided in the United States or its outlying possessions for 10 years, at least five of which were after attaining the age of 16.[1,2]

In the study of migration, citizenship at birth is a fundamental variable of interest. Table 1 reports, in the rightmost column, the actual citizenship at birth of the major categories of persons, by birthplace and parental citizenship. As discussed above, information on birthplace and parental citizenship is not always sufficient for ascertaining citizenship at birth; there are two cases—(i) individual born in the United States to two alien parents, and (ii) individual born abroad to one U.S. citizen parent—in which additional information is needed in order to ascertain citizenship at birth.

Table 1
Citizenship at Birth, by Place of Birth and Parental Citizenship

Place of Birth	Number of U.S. Citizen Parents	Citizenship at Birth
United States	Two	U.S. citizen
United States	One	U.S. citizen
United States	Zero—Born subject to U.S. jurisdiction	U.S. citizen
United States	Zero—Born not subject to U.S. jurisdiction	Alien
Abroad	Two	U.S. citizen
Abroad	One—Requirements to transmit citizenship met	U.S. citizen
Abroad	One—Requirements to transmit citizenship not met	Alien
Abroad	Zero	Alien

NOTES: United States = 50 states, plus outlying territories and possessions to which the United States has extended *jus soli.*

Abroad = Outside the United States.

Nationality at Birth and Citizenship—Mexico

Mexico's law of the land distinguishes between nationality and citizenship. It includes both criteria, *jus soli* and *jus sanguinis* to establish that Mexican nationality is acquired either by birth within the Mexican territory or, regardless of birth place, by being the child of a Mexican father or a Mexican mother or both. Mexican nationality can also be acquired by naturalization. Mexican nationality however, is a neccesary but not a sufficient condition to become a Mexican citizen. A Mexican national by birth needs, a) to be 18 years of age or older or, b) in the case of being born in other country of Mexican parents, or being born in Mexico of both parents being citizens of other country, to have expressly and formally resigned being a citizen of any other country, after being 18 years of age. Such a distinction between nationality and citizenship in Mexico has important implications for patrimonial and job-related rights. The basic assumption behind it is that nationality is part of a heritage that an individual cannot erase even if he or she wants to. In this sense it is like the parents one had, the color of one's skin, language first spoken, religion,

etc. Citizenship, in contrast, derives from fundamental rights of any individual to willfuly select one's allegiance to a nation and government in association to the residence one wants to have on a permanent basis.

Recent (1996) Mexican legislation reforms have introduced unprecedented modalities to the constitutional definition of nationality. Mexican nationality in the past was considered lost when a Mexican national had acquired another nationality. With the new legislation, not yet formaly enacted, Mexican nationality is considered indelible within the Mexican territory, regardless of any other nationalities an individual has acquired. This is the case of a Mexican national who acquires the U.S. nationality/citizenship, who returns to Mexico. As far as the recent reform, such an individual will be considered by the Mexican laws to be as Mexican as when he or she left Mexico. Mexican laws about citizenship however, remain the same. A Mexican national by birth might acquire dual or multiple nationalities without losing his or her original Mexican nationality obtained by either *jus soli* or *jus sanguinis*, when in Mexican territory. However, such an individual cannot have more than one country of citizenship. If such a Mexican national, who has acquired U.S. citizenship, wants to excersize electoral rights in Mexico, he or she has to formaly resign the U.S. citinzenship before being elegible to exercise any electoral right in Mexico.

Notes

1. Note that citizenship acquired via *jus sanguinis* must be maintained through residence requirements, and these have also changed over the years. For example, under the 1940 Act, the child lost his/her citizenship unless he/she resided in the United States for five consecutive years between the ages of 13 and 21.

2. An interesting sidelight concerns the gender requirement for transmitting citizenship. Until 1934, only U.S. citizen men could transmit citizenship to children born to them and an alien parent. The Act of May 24, 1934 (48 Stat. 797) extended the privilege of transmitting citizenship to U.S. citizen women.

Characteristics of Migrants

The Selectivity of International Labor Migration and Characteristics of Mexico-to-U.S. Migrants: Theoretical Considerations

Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor & Paz Trigueros Legarreta

Neoclassical Economic Theories of Migration

Neoclassical economic theories of labor migration posit that individuals situate themselves in the labor market and jobs where their expected earnings (net of migration costs) are highest. Earnings are the product of wages and time worked, both of which depend on education and other "human capital" characteristics of individuals. For example, neoclassical theory predicts that either of the following three events would increase Mexico-to-U.S. migration: (1) an increase in wages or employment for Mexican migrants in the United States; (2) a decrease in employment or wages in rural or urban Mexico; or (3) a decline in migration costs or risks, as when relatives or friends assist villagers with entering and finding work in the U.S. It also predicts that the people who migrate to the

U.S. are those with the set of characteristics that bring them higher expected earnings in the U.S. than in Mexico. Other considerations affecting individuals' satisfaction or "utility" at different locales (e.g., proximity to family members, relative deprivation, family income risk) also affect migration propensities in neoclassical models. The association between characteristics of individuals and their likelihood of migrating is frequently referred to as the "selectivity" of migration.

Four variables are key to explaining the selectivity of Mexico-to-U.S. migration from a neoclassical economic perspective. They are: (1) the economic returns to individuals' characteristics (education, sex, age, etc.) at home (e.g., in the Mexican village); (2) the returns to these characteristics in the United States; (3) the returns to these characteristics in competing migrant labor markets in (e.g., urban) Mexico; and (4) the effects of these characteristics on migration costs. Some theories add to this list the variables of risk (and willingness to take risks) and the utility or disutility of migration for family members besides the migrant (i.e., those who remain behind).

For example, consider a young man with little schooling and few assets in rural Mexico. If the returns to his labor are higher in the U.S. than in his home village or other labor markets in Mexico, there will be an incentive for the man to migrate, other things being the same. If the young man lacks family contacts in the U.S. to help finance the trip northward (including the border crossing) and provide job information, however, higher economic returns in the U.S. may not be sufficient to justify the costs and risks of migrating. In this way, migration selects not only on personal characteristics associated with earnings, including schooling, age, sex, and work experience, but also on household and other contextual variables, including family assets affecting individuals' productivity at home and "migration networks," or family contacts at migrant destinations.

Social science research on the determinants of migration using household-level data generally find that human capital (e.g., education) is positively related to the likelihood of out-migration (see Yap, 1977). The selectivity of migration on individual and household characteristics varies across migrant destinations, however. It depends critically on the returns to these characteristics in different migrant labor markets.

For example, in most cases, average schooling levels for immigrants in the U.S. are substantially above those of their countries of origin (Borjas, 1991 and 1994; Demery, 1986). This finding reflects higher economic returns to schooling in the U.S. compared to places of origin as well as other potential migrant destinations (e.g., urban areas in migrants' countries of origin). It also has implications for development. If migrants take (human) capital with them when they migrate, this may have detrimental effects on the productivity of workers left behind.

Mexico-to-U.S. migration appears to be the exception, however. In the 1980 census, Argentine immigrants to the U.S. report an average of more than 13 years of schooling, compared to less than nine years at home. For Brazil, the differential is even greater: more than 15 years of education for immigrants in the U.S. but less than nine at home. Average education in Guatemala is only around three years, but Guatemalan immigrants in the U.S. average around nine years of schooling. Only in Mexico does the average education of immigrants approach that of the country of origin: roughly 6.5 years of schooling for Mexican immigrants in the U.S. compared with an average of around 6.1 years in Mexico (Borjas, 1991).

The negative selectivity of Mexico-to-U.S. migration with respect to schooling stands in contrast not only to other immigrant groups but also to rural-to-urban migrants within Mexico. Household surveys conducted in Mexico in the 1980s revealed that internal migrants had significantly more schooling than nonmigrants, and that Mexico-to-U.S. migrants had significantly lower levels of schooling than individuals who did not migrate to the United States, including both rural-to-urban migrants and village stayers (Taylor, 1986; Massey, 1987; Massey and García España, 1987; Stark and Taylor, 1991). A typical finding is that average schooling of rural-Mexico-to-U.S. migrants is between 4 and 4.5 years. This pattern appears to be due to high economic returns to schooling for migrants within Mexico, but low returns to schooling both in rural Mexico and in the jobs available to most Mexican immigrants in the United States (Taylor, 1987). In rural Mexico, which has extensive migration networks leading to low-skilled U.S. jobs but where the economic returns to schooling in these jobs are low or nil, the selectivity of international migration strongly favors low-skilled persons. Barriers to legal entry make it difficult for migrants with intermediate levels of schooling to reap high returns in U.S. labor markets.[1]

U.S. Census data generally reveal a continuum of skills for emigrants from Latin American countries, with average schooling lowest for Mexican immigrants, higher for Central American immigrants, and highest for immigrants from the Southern Cone. For example, in 1980, immigrants from Argentina, Brazil, and Canada averaged between 1.2 and 2.7 years more schooling than native U.S. men ages 25 to 64. Immigrants from Guatemala averaged 3.6 fewer years of schooling than native-born U.S. men. Mexican immigrants averaged 6 fewer years of schooling than native-born U.S. men. Of 41 countries of origin in Borjas' (1991) study, Mexican immigrants had less schooling than any other country-of-origin group. In countries other than Mexico, which do not share a long and porous border with the U.S. and do not have extensive networks leading to low-skilled U.S. jobs, international migration is more costly and risky. This precludes much emigration from the low end of the skill distribution, leaving a predominance of brain-drain migrants at the top.

Despite the predominance of low-skilled migrants, there appears to be a significant brain drain at the upper end of Mexico's skill distribution, indicating that the economic benefits from migrating to the United States are sizeable for highly skilled individuals. This outcome is encouraged by U.S. immigration law, which selects migrants on the basis of skills when issuing employment-related visas. As a result, even though most Mexicans, particularly those who enter the U.S. illegally, have low levels of human capital, international migration absorbs a relatively large share of Mexico's educated workforce. In 1994, 843 legal Mexican imigrants reported professional-technical occupations, and 428 described themselves as executives or managers; another 15,290 entered as temporary workers in skilled occupational categories, and 14,773 Mexicans were admitted as students (U.S. INS, 1996). These people constitute a relatively small share of the total flow of Mexicans into the United States and a small share of the skilled U.S. workforce. However, they represent a significant fraction of Mexico's educated workforce. It appears that, although rural-Mexico-to-U.S. migrants have below-average schooling, urban-Mexico-to-U.S. migrants average slightly higher levels of schooling than the national average.[2]

Neoclassical economic theory would predict that migration selects individuals on a wide array of characteristics besides schooling. Traditionally, most of the demand for low-skilled immigrant labor in the United States was in industries with overwhelmingly male workforces (e.g., agriculture). In the past two decades, the demand for female labor in light manufacturing and service (e.g., domestic maid and child care) services in the United States appears to have grown significantly, increasing the economic returns to migration for Mexican women. Village surveys generally find that Mexico-to-U.S. migrants are significantly more likely to be male than non-Mexico-to-U.S. migrants (typically, more than 60-70 percent of Mexico-to-U.S. migrants are males, compared to 30-40 percent of individuals who stay in Mexico, either as nonmigrants or as internal migrants), but that the participation of women in migration is increasing. On average, migrants are also young (first-time migrants usually in their teens, and average age of migrants typically in the late 20s). With few exceptions, Mexico-to-U.S. migrants originate from households in Mexico that are above-average in size—that is, with other family members who can fill in for migrants in household and farm production activities at home. Some studies find that Mexico-to-U.S. migrant households have more physical-capital assets, including landholdings, than non-Mexico-to-U.S.-migrant households, and U.S. migrant households in Mexico almost always average higher income, with or without counting remittances, than nonmigrant households. This suggests that families in Mexico have to reach some minimum wealth or income threshold before they are willing or able to assume the costs and/or risks of sending migrants to the U.S. It also undoubtedly reflects positive effects of past migration

on family assets and incomes. Econometric studies that control for the "feedback" of migration on household incomes reveal that, initially at least, Mexico-to-U.S. migrants tend to originate neither from the very top nor from the very bottom of Mexico's rural income distribution.

Migration Selectivity and Changing Characteristics of Mexico-to-U.S. Migrants

Although socioeconomic differences between migrants and nonmigrants are significant initially, migration network theories (Massey; Stark, Taylor, and Yitzhaki, 1986) predict that these differences narrow as networks of family contacts at migrant destinations expand and the psychological and economic costs and risks of migration progressively decline. This finding helps resolve discrepancies among community studies with respect to some key variables. For example, in contrast to findings reported on pages 748 to 750 (Table 1; also, see Lopez, 1986 and Mines, 1981), some studies have found that migrants are primarily landless workers (Cornelius, 1976; Stuart and Kearney, 1981). Married men dominate the migrant workforce in some towns (Weist, 1973; Cornelius, 1976; Dinerman, 1982), but in others the participation of women and children more closely resembles that of men (Reichert, 1979; Fernandez, 1988; Cornelius, 1990). Without a nationally representative data set, a theory of how average migrant characteristics vary through space and over time is essential for situating and making sense of findings from these community studies.

Massey and Durand (1992), in the sociological literature, and Taylor (1992b) and Stark, Taylor, and Yitzhaki (1988, 1986), in the economics literature, have attempted to incorporate findings from surveys of places into general theories about the process of migration. They emphasize "migration networks" and the diffusion of these networks across sending-area households and individuals as the key variables shaping and reshaping characteristics of migrants over time.[3]

Findings from several community studies in Mexico suggest that migration becomes less selective and more representative of migrant-sending areas over time. This appears to be due to the spread of migrant network connections, which provide information to prospective migrants and offer direct assistance that lowers the material and psychic costs and risks associated with (especially unauthorized) migration across borders. Characteristics of Mexican immigrants increasingly resemble those of the general population as the spread of migration networks within and across communities makes migration less selective. It also makes the origins of Mexican immigrants increasingly diverse, as new networks, fortified in some cases by direct recruitment, materialize in communities that have not traditionally

been major suppliers of migrants to the United States. Because of this, differences in characteristics between migrants and nonmigrants fade over time.

A consensus is beginning to emerge that estimates of migrant characteristics are sensitive to the stage of the migration process at which surveys are conducted. The socioeconomic and demographic profile of migrants from individual villages evolves over time, as does the participation of villages and regions in U.S. migrant streams, in ways that reflect changes in the way individuals are selected into (and out of) migration. The migration selection process shapes the characteristics of migrant flows into U.S. labor markets. This means that estimates of migrant characteristics are a function of the place and time at which surveys are carried out. A survey of migrants from an "old" migrant-sending area generally yields different findings than a survey of migrants from a "new" sending area, and surveys of the same migrant-sending areas produce different findings at different points in time. A statistical portrait of Mexico-to-U.S. migrants cannot be constructed from existing household survey data in isolation of the process that selects people into and out of migration, nor in isolation of the ways in which this process evolves over time.

The ideal way to test for changes in migrant characteristics at different stages of the migration process is to utilize matched longitudinal data, as in the Michoacan Migration Project. Alternatively, Massey, Goldring, and Durand (1994) propose an index of community "migration prevalence" as a basis for comparing communities that are apparently at different stages of the migration process. For a given community at a given point in time, international "migration prevalence" is defined simply as the number of people with international migratory experience divided by the total number of people alive. The disadvantage of the Massey et al. approach is that it imposes a temporal interpretation when explaining differences in communities at given points in time, by assuming that communities have different migration-prevalence levels because they are at different points in a migration process. It is possible for two communities with long histories of migration to have significantly different levels of migration prevalence. The strength of the Massey et al. approach is that it makes it possible to compare characteristics of migrants and nonmigrants in communities with different migration-prevalence levels using cross-sectional data. This is important, in light of the paucity of matched longitudinal data on migrant households. Massey et al. uncover definite patterns of convergence in characteristics between migrants and nonmigrants at different levels of community migration prevalence.

The "New Economics" of Labor Migration

Recent theoretical work on the economics of migration offers additional clues about why characteristics of Mexico-to-U.S. migrants differ from those of nonmigrants and why both change over time. The new economics of labor

migration (NELM; see Massey, Arango, Hugo, Kaouaci, Pellegrino, and Taylor, 1994 and Stark, 1981), suggests four categories of economic motives for migration:

(1) *Expected Income*. Migration (and migrant remittances) are a means to increase incomes of migrants and of their households of origin in Mexico.

(2) *Risk*. Allocating some family members' time to migration provides a way to spread household income risk, by securing access to a new income source that is not highly correlated with local (e.g., crop) incomes. That is, migrants represent an insurance policy for their households in Mexico. The same holds for individuals who are able to spread their work time during the year or across years between Mexico and the United States.

(3) *Market Imperfections*. In the absence of well-functioning capital markets in migrant-sending areas, migrants represent financial intermediaries who enable their households of origin to invest in new activities or technologies.

(4) *Relative Income*. "Investing" in migration is a means for households to improve their relative income position within the reference group (e.g., the village).

These motives for migration are important for explaining changes in immigrant characteristics over time. Motive (1) suggests that migrants originate from poor households with few assets and low productivity (although there are limits to this; see Motive 3, below), and that U.S. migrants tend to be individuals with human capital (skills, schooling) or "migration capital" (e.g., family contacts) for which there is a high economic return in the U.S. (and not human capital for which there is a large economic return in Mexico). Motive (2) suggests that migrants originate from areas where local incomes are risky, or (as emphasized by the NELM) from households that are experiencing economic changes (e.g,. adopting new technologies, changing production activities) that increase (subjective) income risks. However, because migration itself is inherently risky, it also suggests that migrants and their families are able to insure against migration risks, and/or that they have access to "migration networks" that provide migration insurance to them. Motive (3) suggests that migrants have little access to local capital or else that their households of origin have large capital needs relative to capital availability (e.g., if they are investing in new production activities or technologies). However, because migration is costly, it also suggests that families who send migrants abroad have sufficient capital to finance what generally is a costly migration venture, or else have networks of relatives or friends who can finance migration costs from the U.S. side of the border. Motive (4) suggests that migrants originate from households that are relatively deprived within their reference groups (e.g., villages).

The interplay of (1)-(4) suggests that, initially at least, migrants:

- Are individuals with characteristics that make them relatively more productive in the U.S. labor markets to which they have access and less productive in Mexico (i.e., less able to generate income at home.
- Come neither from the poorest households (which cannot afford the costs of international migration) nor the richest households (which lack the expected income and relative income incentives to migrate) in their places of origin.
- Come neither from the least secure households (which would not be willing to take on the risks of migration) nor from the most secure households (which would not depend on migrants for income security).

In the medium- to long-run, the expansion of migration capital, or networks, reshapes the selectivity of migration by influencing the economic returns, costs, and risks of migration. If access to networks becomes diffused across households at different income levels, lower income households may begin sending migrants abroad. Successful migration investments by some families affect the relative income position of others in the local reference group. And, if migrants represent financial intermediaries facilitating investments in new economic activities at home, the absolute and relative income positions of migrant families will tend to rise over time. Finally, catastrophic events in Mexico, such as the economic crisis of the 1980s and 1990s, create incentives for new groups of individuals, with new characteristics, to enter the migration stream. This probably accounts for the rising schooling levels of Mexico-to-U.S. migrants from the Michoacan households depicted in Table 1 on pages 748 to 750.

The Theory of Circular Migration and Imperfect Migrant Labor Markets

It is well known that many of the workers involved in immigration flows into the United States return to their country of origin. In the case of migration from Mexico to the United States, which has persisted for over a hundred years, not only has there been a return flow but it has included the majority of migrants. These workers return to Mexico after a migratory "career" that involves alternating stays in the receiving areas in the United States and in their home communities in Mexico. Such a migratory "career" can continue for several years, but it generally ends with an aging worker's definitive return to Mexico. Obviously this is not true in every case. A growing proportion of migrants is choosing to remain permanently in the United States. Perhaps the decision to remain in the United States or to

return definitively to the home community is a function of the intensity of the interaction between the sending community and the receiving community, reflected in the number of family members that the first-time migrant has in the United States. That is, the fewer family members a migrant has in the United States, the more likely it is that he will return definitively to Mexico.

Data obtained from the Cañón Zapata project support these hypotheses. They reveal a process of circular migration from Mexico to the United States which is clearly related to the geographical proximity of these two countries. By circular migration it is understood here, the process by which an individual alternates stays in Mexico and the United States, for more than six months, between his or her family residence and job residence, until either age, success or failure, makes him or her to permanently establish his family residence at some point of his or her circulatory route, either in Mexico or in the United States.

The notion of circular migration holds methodological and theoretical implications. Methodological, because of at least two reasons, a)length of stays in the United States might be increasingly long, returns to Mexico become increasingly short and job residence becomes permanent as a result of family reunification. Then, new entries to the United States from Mexico might increase the volume of the migratory flow giving to the observer the impression of an increase in immigration to the United States, when in fact he or she is observing an increase in the intensity of a circulatory movement, including Mexican citizens who might have moved on a permanent basis to the United States. On the other hand, b)when measured properly, circulatory migration might become an indicator of the intensity of the interactions between structural conditions and factors located at the two sides of the border, which are associated to the phenomenon of international migration between the two countries. Theoretical, because of at least two reasons. First, the definition of a migrant should no longer depend on his or her position in the map but on his or her engagement in an international labor market. Traditional definitions of a migrant require his or her crossing of a geographical boundary for certain period of time. The notion of a circulatory migration should be made operational from the theoretical assumption that a migrant is a person who is no longer a permanent resident of his or her home town because of a decision that implies to join an international labor market by responding to a perceived labor demand in another country. This means that a migrant is a migrant from the moment he or she has left home with the intention of looking for a job in another country.

The other reason is, that as a consequence of the above, for the purpose of an estimate of the number of international migrants, their numeration should begin when they join the migratory circle, regardless of whether that person has crossed an international border or not. The migratory circle includes the geographical space between the last permanent residence and the place of migratory destiny. The

latter could be of various types—from an attempted destiny to an actually reached one. The analyst's selection of the type of migratory destiny might depend on the scope of the analysis. The important implication here is to include all persons who are in the international migratory circle in the enumeration of international migrants, whether or not they have left the country of origin or reached the country of destination.

Notes

1. One exception to the negative selectivity of international migration with respect to schooling comes from an analysis of one of the newest Mexico-to-U.S. migrant groups, the Mixtecs from Oaxaca (Zabin and Hughes, 1995). It found that, of those who migrated internally to farm jobs in the Mexican states of Baja and Sinaloa, those who went on to migrate to the United States were significantly more likely to be males (84 percent), single (38 percent), and better educated than those who remained as internal migrants in Mexico. (55 percent of the latter were males, 21 percent were single, and average schooling was 2.7 years.) The low mean education of both migrant groups in this sample probably reflects low average schooling levels at these migrants' place of origin in Oaxaca.

2. This conclusion is deduced from (1) the finding from rural household surveys that Mexico-to-U.S. migrants have less schooling than individuals who do not migrate to the United States, and (2) Borjas' (1994) finding that average schooling levels of Mexican-born immigrants in the U.S. (taken from the U.S. Census) are slightly higher than average schooling in Mexico.

3. Taylor (1992) and Stark, Taylor, and Yitzhaki (1986, 1988) emphasize the spread of family migrant contacts, or migration networks, in their theory of changing effects of migration on rural income inequalities. Durand and Massey (1992) emphasize the importance of "social capital," or networks of contacts with family and friends in the United States, in their "cumulative theory of migration."

Characteristics of Migrants

Data Sources

Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor & Paz Trigueros Legarreta

This report has two parts. The first part describes data collected in Mexico. The second part describes data gathered in the United States.

Data Collected in Mexico

This section contains a comparative overview of the ENADID and EMIF surveys; detailed descriptions of each of these two surveys and data sets; and descriptions of Mexican community survey data sets (the Michoacán Survey and the Mexican Migration Project surveys).

ENADID and EMIF Surveys—Introducción

En el presente documento se busca presentar una descripción detallada de las principales fuentes de datos sobre características demográficas y laborales de los migrantes, así como su participación en la práctica migratoria, basadas en muestras de personas o hogares tomadas en México. Las encuestas implementadas en México

que serán revisadas aquí son: (1) La Encuesta Nacional de Indicadores Demográficos (ENADID); (2) La Encuesta sobre Migración en la Frontera Norte (EMIF), (3) Las encuestas llevadas a cabo en el Estudio de Migración de Michoacán de la Universidad de California, Davis, y El Colegio de México; y (4) Las encuestas del Proyecto sobre la Migración Mexicana (el estudio Durand-Massey).

Cada una de las cuatro fuentes de datos tiene características metodológicas diferentes; la ENADID estudia al individuo en su lugar de residencia habitual, ya sea porque está de regreso de su práctica migratoria, o porque su familia señala que se encuentra en Estados Unidos La EMIF se enfoca a los flujos de migrantes, esto es, a aquellas personas en tránsito hacia Estados Unidos o de regreso de ese país, motivo por el cual la información recabada en cada caso es diferente, aún cuando puede ser complementaria. Las encuestas UC Davis-COLEF se enfocan en las características socioeconómicas de migrantes y sus hogares de origín y los impactos económicos de la migración en México. Las encuestas Durand-Massey detallan las características socio-demográficas de la migración y de los migrantes.

Encuesta nacional de la dinámica demográfica, 1992 (ENADID)
(Resumen de la descripción presentada en el CD Rom elaborado por el Instituto Nacional de Economía, Geografía e Informática (INEGI)

Observaciones generales

La Encuesta Nacional de Indicadores Demográficos (ENADID), levantada en 1992,[1] ofrece las siguientes ventajas:

- Se realizó en todo el territorio nacional y tiene representatividad a nivel de entidad federativa, gracias a lo cual se puede conocer el peso de la migración internacional en cada estado de la república y comparar las características de los migrantes con la población no migrante.
- Abarcó tanto a los migrantes de retorno que respondieron a las preguntas sobre su actividad migratoria, como a los que se encontraban en ese país, pero su familia aportaba información sobre algunas de sus características sociodemográficas.

En el caso de los de retorno, se pudo saber algo sobre su historia migratoria, lo que permite conocer los cambios que se han venido presentando a través del tiempo.

Con ella se puede estimar la cantidad de migrantes en el período de 1987 a 1992, conocer datos sobre: fecha de la migración, residencia actual, fecha de retorno, entre otros; y establecer relaciones con la migración interna.

Analizar, además, características educativas, económicas y laborales, de los migrantes, parentesco, sexo, edad, entidad de origen.

Al realizarse en la unidad doméstica de donde provienen los migrantes, también proporciona datos de sus viviendas y grupos domésticos.

Hay que hacer notar que mientras la ENADID incluye a todo tipo de migrantes, —independientemente de la época en que hayan vivido en Estados Unidos y si su permanencia en ese país se debiera a sus actividades laborales o a otro fin— la EMIF, sólo contempló a aquéllos que habían trabajado en Estados Unidos o bien manifestaron su interés por entrar con ese objetivo. Para los fines de este trabajo se excluyó a los entrevistados que declararon no haber nacido en el territorio mexicano, debido a que no había información sobre su nacionalidad.

Para la ENADID utilizamos dos bases de datos del disco compacto elaborado por el Instituto Nacional de Economía, Geografía e Informática (INEGI), la de migración internacional y la de características generales de la población. Analizamos dos bases de datos de la EMIF, proporcionadas por el Consejo Nacional de Población (CONAPO): la de migrantes mexicanos que retornan voluntariamente a México y la de migrantes deportados.

Aunque los migrantes laborales que se dirigen a Estados Unidos provienen de todo el país, a lo largo del tiempo han destacado algunas áreas de origen donde se concentra una alta proporción, en tanto que los demás se dispersan en el resto del territorio mexicano. Tomando en cuenta esta peculiaridad de la práctica migratoria y con la finalidad de tener una visión del conjunto nacional, a partir de las especificidades, dividimos el territorio mexicano en seis regiones, utilizando como criterios:

- La presencia de los oriundos de cada entidad federativa en los flujos migratorios a través del tiempo;
- La intensidad en su participación, de acuerdo a los datos recientes; considerando su peso en el conjunto de migrantes, y, al interior de cada entidad, en relación con su población;
- Su cercanía geográfica.

Complementariamente, se trató de que todas las regiones tuvieran representatividad estadística en la EMIF, ya que, la muestra de varios estados es muy reducida.

Tomando en cuenta estas observaciones se establecieron las siguientes regiones:[2]

I. La región de mayor salida, con 36.7% de los migrantes (de acuerdo a la ENADID), compuesta por los cuatro estados de mayor tradición en esta práctica: Guanajuato, Michoacán, Jalisco y Colima.[3]

II. Las entidades de la frontera norte —Baja California, Sonora, Chihuahua, Coahuila, Nuevo León y Tamaulipas, incluyendo también Baja California Sur[4]— que aportan el 18.3% de los migrantes.

III. Los seis estados ubicados entre las dos regiones anteriores —Sinaloa, Durango, Nayarit, Zacatecas, San Luis Potosí[5] y Aguascalientes— con 18.2% de los migrantes.

IV. Los cinco estados del interior que rodean al Valle de México —Distrito Federal, Estado de México, Querétaro, Hidalgo y Tlaxcala— con 12.9% de los migrantes.

V. Oaxaca, Guerrero, Puebla[6] y Morelos con una participación conjunta de 11.7% de los migrantes.

VI. Las seis entidades del sureste —Veracruz, Tabasco, Chiapas, Campeche, Yucatán y Quintana Roo— que únicamente aportan el 2.2% de los migrantes.[7]

Se utilizó como criterio para clasificar a los migrantes su región de nacimiento, con la finalidad de tener idea sobre algún posible desplazamiento interno antes de migrar a Estados Unidos.[8]

Por otro lado, tomando en cuenta las características de cada encuesta, la información de la ENADID se dividirá, cuando sea pertinente, entre migrantes de retorno y emigrantes (que son los que se encontraban en Estados Unidos cuando se levantó la encuesta). La información de la EMIF se analiza considerando los dos tipos de flujos mencionados:

1. Los que regresaban voluntariamente a México, provenientes de Estados Unidos y que estuvieron en ese país con el fin de trabajar.
2. Los migrantes de origen mexicano entrevistados después de haber sido deportados de Estados Unidos.

Las variables que se analizaron son:

- Edad del migrante,
- Sexo,
- Estado civil,
- Tipo de localidad de nacimiento (urbana o rural),
- Escolaridad,
- Residencia actual,
- Situación laboral del migrante en México, antes o después de migrar, según la información disponible,

- Oficio o profesión desempeñada en caso de haber estado laborando,
- Sector económico,
- Período en que entraron a Estados Unidos por primera y última vez,
- Duración de la última estancia,
- Número de entradas al vecino país,
- Condición laboral y sector económico en el que trabajaron en Estados Unidos, durante su última estancia,
- Estado y ciudad en los que permanecieron más tiempo durante su última estancia.

Metodología

La Encuesta Nacional de la Dinámica Demográfica representa el acercamiento macrosocial más importante y completo al comportamiento demográfico en México. Integra los tres aspectos de la dinámica demográfica (la fecundidad, la mortalidad y la migración), desde el momento mismo del diseño muestral. Es el primer estudio de carácter nacional, que cubre prácticamente todas las zonas del país.

Por su especial cuidado en la metodología utilizada y en los mecanismos de retroalimentación y control, resulta ser una investigación con los más altos estándares de rigurosidad. Su diseño muestral permite cubrir la totalidad del país, generando información a los niveles federal, estatal y municipal.

Comprende catorce temas generales, dentro de tres bloques de aspectos: niveles y composición de la población (características generales de la población, nivel de mortalidad, fecundidad, registro de nacimientos y defunciones y prácticas anticonceptivas); características socioeconómicas de la población (Características de la vivienda, hogares, condiciones económicas y características educativas) y todo lo relacionado con la migración nacional e internacional.

Permite generar datos a nivel nacional, área de residencia urbana-rural, cuatro tamaños de localidad, regiones y entidades federativas.

El diseño de la muestra se realizó de manera estratificada y bietápica. Por un lado se seleccionaron las unidades de acuerdo a condiciones geográficas y características de similitud. Por el otro, las unidades de análisis de acuerdo a dos etapas de selección.

El tamaño de la muestra se calculó atendiendo a dos indicadores: la tasa de mortalidad a nivel nacional y el promedio de hijos nacidos vivos por mujer en edad fértil, a nivel entidad federativa. Para calcularlo se realizó la función en cada uno de los dos conceptos y después se procedió a obtener un tamaño derivado de la

combinación entre los dos factores, calculándose finalmente los niveles de error para los demás temas de interés considerados en la encuesta.

Con respecto a las unidades de análisis, la encuesta comprende las siguientes: las viviendas, los miembros nacionales y extranjeros de esas viviendas, los residentes habituales de las viviendas, las mujeres entre 15 a 54 años de edad, miembros del hogar y residentes habituales, personas que se fueron a vivir a otro país, desde 1987 hasta la fecha de la encuesta y, finalmente, personas que siendo miembros del hogar y residentes habituales murieron de enero de 1987 a la fecha de la encuesta.

El procedimiento de estratificación, pone en primer lugar los municipios o delegaciones de cada entidad federativa. Luego, cada estado se estratifica por Zona Rural, Zona Urbana Certeza (ZUC) y Zona Urbana Resto (ZUR). Finalmente, cada localidad se subdivide en grupos de manzanas.

La estratificación geográfica se realizó de la siguiente manera: se clasificaron localidades de acuerdo al total de habitantes en marzo de 1990, teniendo como resultado cuatro tipos de unidades, las de menos de 2,500 habitantes, las de 2,500 a 19,999 habitantes, las de 20,000 a 99,999 habitantes y las de 100,000 o más.

La importancia de este estudio para conocer la dinámica migratoria, tanto nacional como internacional, aumenta no sólo por la extensión geográfica que cubre, sino también por la amplitud de los temas que están interrelacionados. Permite conocer:

- Las características de los flujos de migración.
- Los perfiles de los migrantes internos e internacionales utilizando la información sobre las características socioeconómicas de los individuos, de los grupos domésticos y de las viviendas.
- Comparar los niveles de migración interna e internacional, con lo que es posible establecer algunas hipótesis de relación entre ambos fenómenos.
- En lo que se refiere a la migración interna, toma en cuenta los aspectos de: la condición de migración (estatal y municipal), el tiempo de residencia en la entidad; el lugar de residencia anterior; tiempo de residencia anterior y el lugar de residencia en 1987.
- En cuanto a la migración internacional, estimar la cantidad de migrantes en el período de 1987 a 1992, conocer datos sobre la condición de residencia al momento de migrar, parentesco de los migrantes, sexo, edad, entidad de origen, fecha de la migración, lugar de destino, residencia actual, fecha de retorno y condición de residencia al retorno.

- Además de este tipo de información, la investigación permitió relacionar la información obtenida sobre las características de la vivienda, las de la población, educativas, económicas y laborales.

Con esta información se agruparon los datos en tres bases distintas: la primera, compuesta por las características generales de las viviendas de los migrantes; la segunda, las características de los flujos de migración interna e internacional y la tercera se compone de las características educativas de los migrantes.

Informe trimestral de la encuesta sobre migración en la frontera norte de México (EMIF)

Introducción

Una de las preocupaciones sobre el estudio del fenómeno migratorio es conocer las características de los individuos que han decidido desplazarse de su lugar habitual de residencia con el objeto de modificar sus condiciones de vida y trabajo. Durante los últimos años este hecho ha llamado la atención de instituciones académicos y por supuesto de las entidades gubernamentales que de alguna manera están relacionadas con la problemática que este fenómeno tiene a su alrededor.

A lo anterior se agrega la necesidad de contar con información oportuna y confiable sobre las condiciones y modificaciones asociadas con los desplazamientos y sobre todo si éstos están orientados a cruzar las fronteras nacionales. En este sentido, la importancia que ha cobrado la migración laboral de origen mexicano a la frontera norte y hacia los Estados Unidos requiere un conocimiento más cercano de sus componentes para que, en la medida de lo posible, se ejecuten acciones de Política Pública encaminadas a modificar o atenuar las causas que originan tales movimientos.

En este contexto, la Encuesta sobre Migración a la Frontera Norte de México (EMIF) proporciona información que permite evaluar los posibles cambios en el comportamiento de la población migrante, así como para la realización de estudios comparativos. El objecto de La Encuesta sobre Migración en la Frontera Norte (EMIF), es captar la dimensión y características de los distintos flujos de migrantes laborales mexicanos, a partir de la elaboración teórico-metodológica desarrollada por el equipo encabezado por Jorge Bustamante, con Jorge Santibáñez y Rodolfo Corona, todos ellos de El Colegio de la Frontera Norte. Su finalidad es estudiar la circularidad migratoria basada en el método de muestreo de poblaciones móviles. En ella, se utiliza el concepto de migrante laboral a partir de su conducta de migrar, esto es, de desplazarse de su ciudad o comunidad de residencia de origen a otra ciudad o comunidad con propósitos laborales. El flujo migratorio se concibe así

como un desplazamiento o más que un "migrante" realiza a través de una ruta recurrente de su lugar de origen a otra ciudad, estado o país y viceversa, con propósitos laborales o para regresar de manera temporal o definitiva. Se trata de una encuesta continua, por lo que permite captar las variaciones durante el año, tanto en el número de migrantes como en la participación de los distintos subgrupos. La encuesta tuvo dos etapas, la primera, de 1993 a 1994, y la segunda, de 1994 a 1995. Sólo se trabajó la información del primer año, pues es la única disponible.[9]

Dada la metodología de la EMIF, los levantamientos anuales pueden dividirse en cortes trimestrales. El presente documento informa, sobre los resultados obtenidos durante el trimestre comprendido entre el 14 de diciembre de 1993 al 13 de marzo de 1994, correspondiente al primer levantamiento.

En el primer apartado se exponen consideraciones en torno a la metodología que sustenta a la encuesta y la información relevante sobre el trabajo de campo. En un segundo apartado se presentan los elementos que permiten contar con una definición de población de trabajo, que en adelante se denominará población de análisis.

Con base en lo anterior el tercer apartado contiene la descripción de algunos resultados de la encuesta. El orden de presentación de los mismos tiene por objetivo ofrecer un panorama general de las características de la llamada población migrante y de cada una de las particularidades asociadas a ella. En este sentido conviene señalar que la encuesta capta migrantes que se desplazan por diversos motivos, sin embargo en el presente documento la atención se centrará en los migrantes laborales captados por la encuesta.

De igual manera el documento considera, en primer lugar, una caracterización general por flujos y subpoblaciones de análisis para el leventamiento trimestral.

Finalmente se presentan un anexo estadístico. El cual tiene un formato que responde a distintas necesidades, El Anexo I está conformado por la serie de tabulados básicos de los migrantes laborales durante el trimestre considerado del primer levantamiento por flujo y subpoblación. La caracterización general de los migrantes que dan origen a cada subpoblación de análisis, se basa en esta información.

Descripción general de la EMIF

Consideraciones generales

La Encuesta sobre Migración en la Frontera Norte de México (EMIF) es una fuente de medición y caracterización directa de los flujos migratorios de trabajadores mexicanos en dos direcciones: a) entre México y Estados Unidos y b) hacia o desde las localidades fronterizas del norte de México. La base metodológica de la EMIF, aplica técnicas de muestreo probabilístico de poblaciones móviles y supone

una observación directa que cubre un amplio espectro de posibilidades tipológicas de desplazamientos migratorios.

Por esta razón la EMIF incorpora dos dimensiones en la medición del fenómeno migratorio, la geográfica y la temporal, lo cual representa la posibilidad de una observación continua de los desplazamientos en ambas direcciones y en consecuencia un tratamiento especial de las mediciones que se vayan registrando.

Los elementos que la metodología de la EMIF conjuga son:

I. La captura y estudio de los desplazamientos migratorios, en ambas direcciones.

II. La analogía con el tipo de desplazamientos estudiados por otras disciplinas como la oceanología o la biología que miden los desplazamientos periódicos, estacionales o cíclicos de individuos de un lugar a otro.

El flujo de personas se presenta en ambas direcciones[10] (Sur-Norte), lo cual hace compleja y poco operativa la agrupación en un solo conjunto a las personas que comprende dicho flujo, además que las características pueden variar para quien se incorpora a éste o sale del mismo[11]. Esta doble dirección del flujo migratorio, requiere una clasificación que permita una observación y caracterización adecuada del mismo.

Los migrantes cuya dirección es de sur a norte llegan a una localidad fronteriza ya sea para permanecer en ella o para cruzar (documentado o indocumentado) hacia Estados Unidos. Los migrantes en dirección norte-sur, llegan a las localidades fronterizas procedentes de Estados Unidos (de manera voluntaria o devueltos por la patrulla fronteriza) o de las mismas localidades fronterizas, utilizándolas como punto de salida hacia el sur, o como destino o inicio para un nuevo cruce hacia Estados Unidos. Esta dinámica es la que se conoce como flujo migratorio.

La división del flujo migratorio propuesta por la metodología de la EMIF, segmenta a los migrantes dependiendo de su dirección y destino, definiendo la población objetivo y la población sujeta a observación captada en cada una de las encuestas de la manera descrita por el cuadro no. 1.

Es importante resaltar que para cada una de las subdivisiones propuestas en el diseño de la EMIF, se aplican cuestionarios diferentes toda vez que se realizan los filtros para identificar la población objetivo a la que pertenecen los sujetos encuestados (ver diagrama de la cédula filtro de la EMIF).

La EMIF consta de cuatro cuestionarios diseñados para captar a migrantes en ambos sentidos. A los deportados se les identifica como un flujo en sí mismo, ya que en el cuestionario para estos migrantes se excluyen preguntas que permitan subdividirlos, pues la característica para identificarlos es que su regreso se califica como forzado.

Cuadro 1

Población	Flujo Migratorio: Procedente del Sur y con Destino: Estados Unidos	Flujo Migratorio: Procedente del Sur y con Destino: La Frontera Norte	Flujo Migratorio: Procedente del Norte: Estados Unidos	Flujo Migratorio: Procedente del Norte: La Frontera Norte	Deportados
Población Sujeta a Observación	Todas las unidades sujetas a muestreo, es decir, toda persona que pasa por los puntos de muestreo, independientemente que pertenezcan o no a la población objetivo.				
Población Objetivo: Individuos que participan en el flujo migratorio Internacional o a la frontera norte de México	Individuos no nacidos en Estados Unidos, mayores de 12 años que llegan a una de las ciudades por las zonas y puntos de muestreo considerados, no residentes en esa ciudad y cuya estancia en la zona fronteriza es para trabajar o buscar trabajo, para visitar familiares o amigos, o por negocios, sin fecha comprometida para el regreso. (1)		Individuos mayores de 12 años, no nacidos en Estados Unidos, que no viven en la ciudad de aplicación de la entrevista, cuya estancia, mayor de un mes, en la zona fronteriza se debió a una visita a familiares, amigos, o bien a negocios; o para buscar trabajo o trabajar, independientemente de la duración de su visita. (2)		ndividuos que son entregados a las autoridades migratorias mexicanas por agentes de la patrulla fronteriza de Estados Unidos, en los puertos de entrada al país, ubicados a lo largo de la línea fronteriza.

1. Si manifiestan la decisión de ir a los Estados Unidos con o sin experiencia migratoria internacional o de permanencia en la ciudad fronteriza pero con alguna experiencia en migración internacional, se considera migración internacional; al complemento de éste conjunto, se le considera migración a la frontera norte.

2. Si la mayor parte del tiempo permaneció en alguna ciudad de Estados Unidos, se considera como un desplazamiento procedentes de dicho país. En caso contrario, si la mayor parte del tiempo permaneció en alguna localidad fronteriza del norte de México, se juzga como desplazamiento procedente de la frontera norte.

Por lo anterior, en adelante se ha determinado utilizar la siguiente clasificación de flujos y subpoblaciones de análisis,[12] misma que será utilizada para referirse y presentar los resultados de la encuesta.

Para el flujo sur-norte se presentan como subpoblaciones aquellos cuyo destino es la frontera norte y/o los Estados Unidos.

En el caso del flujo norte-sur, se consideraron como subpoblaciones tanto a quienes proceden de Estados Unidos como a los que proceden de la frontera norte de México. A los migrantes devueltos por la patrulla fronteriza se les denominará flujo de Deportados.

1. Flujo Sur-Norte

   — Con destino a la frontera norte *(SFN)*

   — Con destino a los Estados Unidos *(SEU)*

2. Flujo Norte-Sur

   —Procedentes de Estados Unidos *(EUS)*

   — Procedentes de la frontera norte *(FNS)*

3. Flujo Deportados

   — Deportados *(DEP)*[13]

En relación con la clasificación propuesta concierne anotar las siguientes precisiones.

Flujo Sur-Norte. Capta sujetos cuya estancia en la zona fronteriza se debe a visita a familiares o amigos y negocios, sin fecha comprometida de regreso y por eso es mayor que el flujo migratorio laboral. La razón por la que se incluyó es que, si bien al momento de la entrevista no es migrante por motivos laborales, con el paso del tiempo puede convertirse en uno.

Dentro de este flujo no se consideran aquellos sujetos que declaren como lugar de residencia alguna localidad en los Estados Unidos, toda vez que son excluidos de la encuesta a partir de la cédula filtro.

Flujo Norte-Sur. Capta sujetos nacidos en México que residen actualmente en los Estados Unidos. Sin embargo no puede ser considerada representativa de la población nacida en México y residente en Estados Unidos, puesto que se desconoce el porcentaje de esa población que se desplaza a México en forma temporal; tampoco se conoce si el sujeto de esa población que se desplaza temporalmente tiene un perfil similar a quien no lo hace.

De igual modo, capta flujos migratorios no necesariamente laborales, ya que se aplica un cuestionario a aquellos sujetos cuya estancia en Estados Unidos fue para visitar a familiares o amigos o para negocios, con tiempo de estancia superior a un mes.

Flujo Deportados. Incluye ciudadanos de otras nacionalidades, residentes de la zona fronteriza y aquellos sujetos cuyo desplazamiento se efectúa por motivos no laborales (compradores, personas que visitan familiares o amigos, etcétera). Subestima a los menores de edad, ya que éstos son frecuentemente entregados a los consulados de México en Estados Unidos para su repatriación.

Otro aspecto importante es que de las unidades en flujo, aquí es donde la probabilidad de que se presente una enumeración múltiple es más alta, pues los

migrantes realizan varios intentos consecutivos hasta lograr internarse en Estados Unidos o desistan de su intento.

Por las características del diseño metodológico de la EMIF, existen algunos tipos de migrantes laborales que no son captados por la encuesta, estos son los que se desplazan en transportes marítimos desde México hacia los Estados Unidos, en transportes de carga, en vehículos particulares, en transportes aéreos que llegan directamente a ciudades del interior de los Estados Unidos de América y los residentes en la frontera que deciden migrar a los Estados Unidos. Asimismo los llamados *commuters* y los *visa abusers.*[14]

Dado que la EMIF realiza una ponderación con base en dos dimensiones (espacio y tiempo) para expandir las características del migrante, conviene señalar que los eventos presentan variación de representatividad que depende en primera instancia del tiempo y el espacio donde se detecta el desplazamiento, así como de la dinámica del flujo en el punto donde se aplica el cuestionario.

Avances en el desarrollo del levantamiento de la EMIF

La EMIF consta de levantamientos anuales continuos divididos en períodos trimestrales. Hasta el momento se cuenta con la información de los cuatro trimestres para el primer año de levantamiento.

Las fechas de estos levantamientos son como se presenta en el cuadro no.2. Uno de los aspectos que interesa destacar es el relacionado con el procedimiento del levantamiento de la EMIF.

Primer año de levantamiento

En el primer año de operación de la encuesta, se establecieron tres regiones de muestreo;[15] la región Este que comprende las localidades fronterizas situadas al este de Ciudad Acuña, Coahuila; la región Centro con las localidades ubicadas

Cuadro 2
Períodos trimestrales
Primer levantamiento

	1er. Trimestre	2o. Trimestre	3er. Trimestre	4o. Trimestre
1er. Levantamiento				
28 de Marzo 1993	28/Mar/1993	28/Jun/1993	28/Sep/1993	28/Dic/1993
27 de Marzo 1994	27/Jun/1993	27/Sep/1993	27/Dic/1993	27/Mar/1994

entre Ciudad Acuña y Nogales y la región Oeste que comprende las localidades situadas al oeste de Nogales. Tales regiones se organizaron a partir de siete ciudades de la frontera norte que fueron elegidas como los puntos de coordinación de la encuesta.[16]

En este el primer año de operación (28 de marzo de 1993 al 27 de marzo de 1994), la distribución de las localidades donde se aplicó la encuesta se detalla en el cuadro no. 3. La dinámica del movimiento de los diferentes flujos captados obligó la modificación de las localidades de muestreo debido al cierre de operaciones en ellas, ésta situación se refleja en la variación del número de localidades reportado.

Durante el segundo trimestre de operación, se eliminaron definitivamente cinco localidades: Cd. Guerrero, Agua Prieta, Naco, Ojinaga y Sonoyta, por lo que el trabajo de campo se realizó en 18 localidades.[17]

Cuadro 3
Distribución de localidades de muestreo por region y coordinacion regional: Primer levantamiento anual
(28/Mar/93 al 27/Mar/94)

Region	Coordinacion Regional	Localidad
Este	Matamoros	Matamoros R. Bravo/Nvo. Progreso Reynosa Camargo Miguel Alemán
	Nuevo Laredo	Nuevo Laredo
	Piedras Negras	Piedras Negras Ciudad Acuña
Centro	Juárez	Cd. Juárez Porfirio Parra Rodrigo M. Quevedo Porvenir
	Nogales	Nogales
Oeste	Mexicali	Mexicali San Luis Río Colorado
	Tijuana	Tijuana Tecate

Dentro de las localidades se establecieron zonas de muestreo (central de autobuses, aeropuertos, estaciones de ferrocarril, garitas), y dentro de las zonas puntos de muestreo. Estos puntos de muestreo son los lugares donde se aplica la encuesta dado que las personas que utilizan los servicios de transporte público pasan obligadamente por ellos.

Los puntos de muestreo son las puertas de entrada o salida a los andenes, salas para recoger equipaje, etc. En el caso de los deportados éstos puntos son las puertas por donde la patrulla fronteriza devuelve a territorio mexicano a las personas que se internan ilegalmente a los Estados Unidos.

Durante el primer año de aplicación de la EMIF, la distribución de los puntos de muestreo establecidos se presenta en el cuadro no.4.

Durante el primer trimestre de operación la distribución de los puntos de muestreo se detalla en el cuadro no. 5.

En lo que se refiere al número de cuestionarios aplicados, EL COLEF reportó la siguiente distribución en el primer año, según los flujos identificados en el cuadro no. 6.

Durante este año de aplicación de la EMIF, la evolución en el levantamiento de los datos para el primer trimestre de acuerdo al sentido del flujo, se presenta en el cuadro no. 7.

Durante el segundo trimestre, la aplicación de cuestionarios observó la distribución que aparece en los cuadros 8 y 9.

Definición de población objetivo

Dentro de la corriente migratoria confluyen personas cuyos desplazamientos hacia o desde la frontera norte o los Estados Unidos responden a diversas razones. Dado que uno de los objetivos centrales de la EMIF es la captación de los desplazamientos de carácter laboral, conviene considerar las principales características se presenta en el cuadro no. 10.

De acuerdo con el cuadro anterior se puede clasificar a la población migrante en dos grupos diferenciados entre sí: uno conformado por individuos nacidos y residentes en México que declararon como razón del desplazamiento trabajar

Cuadro 10
Población migrante
Individuos que participan en el flujo migratorio internacional o a la frontera norte

Migrantes Laborales	Migrantes No Laborales*
Individuos nacidos y residentes en México que declararon como razón del desplazamiento trabajar o buscar trabajo	Individuos que declararon como razón de desplazamiento una actividad ajena a trabajar o buscar trabajo.

* En este flujo están considerados extranjeros residentes en México y que declararon como razón de desplazamiento trabajar o buscar trabajo.

o buscar trabajo, y el otro integrado por quienes declaran que lo hacen por razones diferentes.

El objetivo es captar a los mexicanos nacidos en México, que vivían y que residían en México pero en lugares diferentes a las localidades fronterizas, especialmente a quienes declararon como razón de desplazamiento trabajar o buscar trabajo.

Con base en lo anterior se sugiere como definición de *migrante laboral* al conjunto de individuos captados por la EMIF, que siendo parte de la población migrante han nacido y residen en México y que declararon como razón del desplazamiento trabajar o buscar trabajo. En adelante nos referiremos a los grupos por la denominación de migrante laboral y de migrante no laboral.

De acuerdo con esta definición no se incluye como migrante laboral hacia Estados Unidos a quien:

a. Declara que se desplaza a los Estados Unidos por actividades no relacionadas con trabajar o buscar trabajo, aunque cuenten con experiencia migratoria hacia ese país.

b. Declara que se desplaza a la frontera norte y declara no ir a buscar trabajo, pero tiene experiencia migratoria en los Estados Unidos.

c. Declara que se desplaza a la frontera norte y no contestó o no especificó si va a trabajar o buscar trabajo a la frontera norte aunque tenga experiencia migratoria hacia los Estados Unidos.

d. Declara que se desplaza a los Estados Unidos por actividades no relacionadas con trabajar o buscar trabajo y que además no tiene fecha comprometida de regreso.

También se excluye como migrante laboral hacia la frontera norte a quien declara que se desplaza a la frontera norte por actividades no relacionadas con trabajar o buscar trabajo, pero no tiene fecha comprometida de regreso.

Con objeto de caracterizar a los migrantes laborales se han considerado las siguientes variables:

- Sexo
- Edad
- Escolaridad
- Estado civil
- Jefe de hogar
- Localidad de residencia

- Estado de residencia
- Ciudad de cruce
- Estado de mayor permanencia en Estados Unidos
- Localidad de destino
- Estado de destino
- Documentación para cruzar a Estados Unidos
- Documentación para trabajar en Estados Unidos
- Empleo-desempleo en Estados Unidos
- Empleo-desempleo en México 30 días antes de iniciar el viaje

Finalmente conviene hacer una aclaracion en relación con la forma en que se presenta la información.

La primera se refiere a la dificultad para presentar una división a partir de la variable sexo y utilizarla como base de comparación debido a que la muestra tiene una proporción pequeña de mujeres. Por tal razón se optó por realizar la comparación por tipo de localidad de residencia (urbana-no urbana).

El papel de la frontera norte en el fenómeno migratorio

Una de las preocupaciones básicas del fenómeno se relaciona con las variaciones en el tiempo que presenta la corriente migratoria hacia y desde la frontera norte de México y los Estados Unidos. Si bien es cierto que a lo largo del año los movimientos de personas están presentes, es durante algunas épocas donde dicha corriente tiende a ser más intensa en cualquiera de las dos direcciones.

En este sentido, diversos especialistas afirman que durante los meses de enero y febrero, aumenta la corriente migratoria hacia el norte a causa del regreso de connacionales hacia los Estados Unidos y por la presencia en las ciudades fronterizas de aquellos que intentan cruzar hacia ese país, generalmente de manera indocumentada. De acuerdo con los datos presentados para este período, es el flujo sur-norte el de mayor importancia ya que concentra un mayor porcentaje respecto a los flujos norte-sur y deportados (45.9%, 33.7% y 20.3% respectivamente).

Tamayo y Fernández (1983), sostienen que la heterogeneidad interna de la frontera norte complica identificarla como una "región"; el único elemento de homogeneidad fronteriza es su desigualdad manifiesta respecto a los niveles de desarrollo estadounidense.

Las desigualdades en el desarrollo económico entre las zonas de la región fronteriza, repercuten en la dinámica de los mercados de trabajo locales. Esta dinámica es uno de los principales elementos de atracción de la migración laboral. La distancia geográfica entre la región de origen y destino también repercute en las actividades que los migrantes desarrollan en sus localidades de origen así como las que están en posibilidades de desarrollar en las de destino.

La frontera norte se ha caracterizado por ser una de las regiones de atracción de las migraciones internas de este país. Dentro de ésta, existen algunas zonas urbanizadas más significativas como destino de migrantes, como el caso de Tijuana que presenta un importante crecimiento demográfico y un fuerte desarrollo económico; donde los sectores comercial y servicios son básicos para la economía, sin olvidar que el sector industrial presenta un gran dinamismo a partir de la instalación de la industria maquiladora.

Por su parte, Nuevo Laredo conjuga ser la puerta de entrada más cercana hacia los Estados Unidos desde la Ciudad de México, amén de encontrar en esta ruta a la ciudad industrial de Monterrey. Ambos elementos hacen de Nuevo Laredo un importante centro de tráfico comercial entre México y los Estados Unidos

Ciudad Juárez y Nogales, desarrollaron su dinámica económica a partir de la década de los setentas, principalmente por el establecimiento de la industria maquiladora que atrajo una importante corriente de migración laboral.

Matamoros, Piedras Negras y Mexicali, se consolidan a partir del auge que tuvieron sus valles agrícolas y el efecto que tuvo la reactivación económica en las ciudades fronterizas al término de la Segunda Guerra Mundial, junto con el impulso que recibieron sus economías a partir de la implementación de la industria maquiladora.

Muestras de la población migrante

Primer levantamiento[18]

Consideraciones generales. Durante el trimestre comprendido entre el 14 de diciembre de 1993 y el 13 de marzo de 1994, la EMIF captó para la población migrante los siguientes totales en cuadro no. 11.

Del total registrado para la población migrante captada por la EMIF, la distribución de acuerdo a los grupos y flujos asociados se detalla en los cuadros 12 y 13.

Tomando el total estimado para la población migrante, los definidos como laborales, es decir aquellos nacidos y residentes en México que declararon como razón del desplazamiento trabajar o buscar trabajo, representan el 61.03% del total captado en este período, mientras que los identificados como no laborales representan el 38.97%.

SFN: Procedentes del Sur con destino frontera norte

SEU: Procedentes del Sur con destino Estados Unidos

EUS: Procedentes de los Estados Unidos con destino al Sur

FNS: Procedentes de la frontera norte con destino al Sur

DEP: Migrantes deportados

Si consideramos que la frontera norte ha experimentado un crecimiento demográfico que destaca en comparación con el resto del país (Ham, 1993), no es de extrañar que para ambos grupos (laborales y no laborales), mayor número de ellos se dirige a localidades de la frontera norte en contraste con aquellos que se dirigen a los Estados Unidos. Aquí se destaca que el 54.73% de los migrantes laborales participantes en el flujo sur-norte se dirigían a alguna localidad de la frontera norte y el 63.42% de los migrantes no laborales tenían este mismo destino.

Tal hecho se explica en parte, por el atractivo para la migración de las condiciones laborales que se han desarrollado en la frontera, y del importante papel que han desempeñado estas ciudades en el marco de la crisis económica de los ochenta.[19] La importancia económica de la región parece confirmarse también en el caso del flujo norte-sur ya que la proporción de migrantes laborales que proceden de la frontera norte significó el 61.18% del total del flujo.

DEP: Migrantes deportados

Considerando el total de migrantes no laborales con dirección norte-sur destaca que el 70.13% provenía de alguna ciudad de los Estados Unidos.

La EMIF reporta que del total de migrantes laborales, el 20.36% son deportados.

Como primera observación, se destaca que la mayor proporción de migrantes participa en el flujo sur-norte (43.69%), en el flujo norte-sur participaron el 39.94% y los deportados representan el 16.37% restante. La mayor proporción (25.27%) son migrantes que tienen como destino la frontera norte, seguidos en orden de importancia por aquellos que provenían de Estados Unidos (21.57%).

Del total de los migrantes laborales captados durante este período el 25.13% se dirigió hacia la frontera norte y el 20.78% a los Estados Unidos. El 20.63% provenía de la frontera norte y un 20.37% fueron captados como deportados.

De los migrantes no laborales la subpoblación más representativa es aquella que proviene de los Estados Unidos (34.86%).

Perfil básico de los migrantes laborales. A partir de las variables consideradas en este documento como básicas[20] y del conjunto de datos de la EMIF para el período, se pueden identificar los rasgos más distintivos de la población laboral que capta la encuesta. Los migrantes nacidos y residentes en México, que se

desplazaron para trabajar o buscar trabajo entre el 14 de diciembre de 1993 al 13 de marzo de 1994 tienen las siguientes características: El flujo sur-norte muestra un peso relativo mayor (45.92%) que el del flujo norte-sur (33.72%) en el total de los desplazamientos por motivos laborales. Al observar las subpoblaciones se tienen que el movimiento más significativo del flujo sur-norte es aquel que se dirige a la frontera norte (54.73%), en el flujo norte-sur los que provienen de la frontera representan el 61.18% (Cuadro no. 13).

The Michoacán Project Surveys of 1983, 1989, and 1993 (Taylor, Fletcher, Orlove, and Yúnez)

The Michoacán household-farm surveys were carried out in three villages and a town in the Pátzcuaro region in spring/summer of 1983, 1989 and 1993. This region is located in central Mexico, approximately 1,500 miles south of the Mexico-California border. It is on the fringes of the Tarascan highlands. Like most of central Mexico, it is at an altitude of more than 6,000 feet. The villages and town are situated on the shore of Lake Pátzcuaro. At the time of the 1983 survey, two of the villages were connected to the nearest town, Erongarícuaro, by a dirt road which

became impassible to all but off-road vehicles during much of the rainy summer season. The 1983 survey gathered data on 540 individuals in 61 randomly selected households located in two villages. In the 1989 and 1993 surveys, we re-interviewed these original households, and in 1993 added 20 new households to the sample in each village and expanded the survey to a third village and nearby town, with a sample size of 50 households in each.

This region has a long history of sending migrants to the United States, predating the bracero program. Migration accelerated during the bracero program. In many villages, well over one half of all men who were in their prime working years during the 1950s and early 1960s participated at some time in the bracero program. Most of these also entered the United States illegally to work during this period. A typical pattern was for young men to first work in U.S. agricultural jobs as braceros, returning to their villages each year and using U.S. earnings to invest in their farms and raise their families in Mexico; then to regularly enter the United States illegally to work each year. The termination of the bracero program did not reduce Mexico-to-U.S. migration from the villages in this study. Instead, ex-bracero workers continued to cross the border frequently in the 1960s to work in the fields as unauthorized immigrants. Their treks northward became less frequent in the 1970s and especially in the 1980s, as the ex-braceros became older and as their children took their place in U.S. labor markets.

With very few exceptions, at least one son or daughter of ex-braceros, and typically several children, were residing in the United States at the time of our first survey. However, few held agricultural jobs; most (around 90 percent) worked in light manufacturing and service jobs in and around Southern California's San Fernando Valley. By the early 1990s, the numbers of U.S. migrants increased dramatically, as older siblings helped younger ones to migrate and as many children of non-ex-braceros joined U.S. migrant streams.

One of the villages, a Purépecha (Tarascan)-speaking community, was almost entirely bypassed by the bracero program. Its households did not participate heavily in Mexico-to-U.S. migration at the time of the 1983 survey; only a handful of individuals from this village worked in the United States in the early 1980s, almost all as H-2 workers harvesting tobacco in Virginia. By 1993, many households in this village had family members working in the United States, mostly in manufacturing and service jobs in Southern California, a few harvesting apples in Washington and Oregon, but no H-2(A) workers in the Eastern United States.

The villages boast several tienditas, or small stores, in which goods brought in from the outside are sold through windows cut into the facades of adobe houses. These goods range from flour, lard and sugar to Coca Cola, toilet paper and

chewing gum. Typically, a local butcher slaughters an animal and sells meat on the main cobbled road in the village once every one or two weeks. The rest of the time, villagers must travel the one to two kilometers to town to purchase meat. Stores in the town also sell a limited variety of consumer durables, and a weekly market dramatically expands the town's inventory. There is no central market within the villages. Apart from the *tienditas*, an active trade in staples, dairy products and some fruits and vegetables is carried out on doorsteps of village houses. Villagers have excellent information about which families have maize surpluses, milk cows, chickens and eggs, firewood and other local commodities for sale in the village. Local prices for these commodities are held in check by the villages' proximity to the town. The interaction of village supply and demand determines the prices of other goods, including labor and tractor services, which are supplied locally.

High transaction costs insulate the villages and town from much of the influence of government corn-price policy. Despite a high government-guaranteed price for maize, the cost of transporting harvests to the nearest CONASUPO purchase point prevented all but a few individuals from selling to the government. Relatively marginal agro-ecological conditions limited maize output in this area to around one metric ton per hectare, restricting the local maize supply. As a result, local corn prices were lower than the guaranteed price but nevertheless well above the world price during this period.

The household-farm survey gathered complete sociodemographic data on every living family member, regardless of whether he or she was residing in the village at the time of the surveys. These data include sex, age, education, marital status, migration experience for both internal and international migration, relationship to the household head, current residence and years at current residence, English language proficiency, and U.S. immigration status. We also constructed a complete work time-use profile on every family member residing in Mexico, and we gathered data on all income contributions to the household from migrants in Mexico or in the United States, including in-kind contributions.

The surveys included a module on household assets (land, physical capital, contacts with relatives and friends elsewhere in Mexico or in the United States). Complete data were also gathered to permit estimation of production, incomes and expenditures each household in the sample. On the production side, village market prices (where available) and quantities of all intermediate and factor inputs and outputs were recorded for each activity. For subsistence households, production was valued at the going village price.

On the factor side, wages for hired labor and, except in the case of a few tractor owners, actual costs of tractor services were observed and used to calculate

hired-labor and capital value-added. Ox-and-plow services were valued at their opportunity costs, that is, the village price for these inputs. The ejido, or agrarian reform, prohibited sale or renting of *ejido* lands, which made up nearly all of the land base controlled by villagers. Because of this, land rents had to be estimated econometrically. (See Taylor and Wyatt, 1994). Family labor value-added was calculated as a residual, from the imputed value of production minus the observed or imputed costs of all intermediate and factor inputs, including imputed land rents. (Land rents were not separated out from family and other capital in the 1982 SAM.) All purchases of inputs and sales of output were recorded by origín and destination, respectively. Inputs purchased from outside the village represent "village imports," while output sold to outside markets represents "village exports." The difference between exports and imports yields village marketed surplus, which is a village analogue to the marketed-surplus concept in the household-farm literature (e.g., Singh, Squire and Strauss, 1986).

The expenditure side of the survey gathered data, based on recall and a reconstruction of typical weekly food menus, on consumption expenditures, savings and investments. Expenditures on lumpy goods like furniture, plows, and house construction were relatively easy to obtain, as was information on daily or weekly menus, e.g., the corn input into a family's nixtamal (dough) for *tortillas*. In the case of subsistence production, consumption, like output, was valued at village market prices. Expenditures on livestock, machinery and tools made up the majority of investments. These expenditures, together with limited reported savings in bank accounts, were counted as savings (payments by households into the capital account) and as investments (expenditures by the capital account on investment goods or savings sent to banks outside the village) in the village SAM. No formal savings were reported in the 1988 survey, which was for a period of high inflation and negative real interest rates. Schooling expenditures were counted both as human-capital savings (from households to the human capital account) and as human-capital expenditures (from the human capital account to the rest of Mexico). Children normally complete six years in a government school within the village. Because primary education is free and secondary schools are located outside the village, human capital investment represents a village import. Schooling costs include fees, supplies, lodging for live-away students (e.g., in the state capital of Morelia), and daily transportation for students commuting from the village to the government secondary school in the nearby *municipio* (county) seat of Erongarícuaro or to a post-secondary school in the city of Pátzcuaro. All consumption and investment expenditures were recorded by place of origín to indicate whether they represent local goods or village imports.

Mexican Migration Project (Durand-Massey) Surveys

The Mexican Migration Project provides cross-sectional data from random samples of households surveyed in 1982-83 and 1987-91 in 19 communities in the Mexican states of Jalisco, Michoacán, Guanajuato, and Nayarit, areas that have traditionally sent large numbers of migrants to the United States. Within each community, 100-200 households were randomly selected and interviewed, resulting in a total sample size of 3,400 households across 19 communities. Detailed sociodemographic data were gathered, together with migration life histories.

Data Collected in the United States (Census, Current Population Survey, INS, and Farmworker Surveys)

United States Census and Current Population Survey

The U.S. decennial censuses and the Current Population Surveys (CPS) are among the major sources of data used by researchers to study the characteristics of migrants. Public-use microdata files are available for the censuses of 1900, 1910, and 1940 through 1990.

Strengths of the U.S. Decennial Censuses

The decennial Census of Population enables rich description of the enumerated foreign-born. Information on country of birth, year of entry, naturalization, and, in some censuses, on use of English or other languages and on parental nativity can be combined with data on age, sex, marital and employment behavior, and earnings and income to yield a composite picture of the foreign-born at the time of the census. The censuses also have the advantage of broad coverage and ample sample size, facilitating examination of groups whose size is very small, such as age/sex/nationality-specific cohorts.

Shortcomings of the U.S. Decennial Censuses

Unfortunately, the inferences about the migration process that can be drawn from census data are limited, due to three serious shortcomings: (a) the lack of information on characteristics particularly relevant to the study of migration, (b) the census data's cross-sectional nature, and (c) lack of firm knowledge concerning the rate and stability of coverage.

Missing Migration-Relevant Information

As is well known, the decennial censuses do not contain information on the *legal status* of the foreign-born.[21] It is thus impossible to distinguish among true immigrants (legal permanent resident aliens and those among them who have become naturalized citizens) and visitors of a wide variety. Some of the visitors are nonimmigrants, i.e., persons holding *temporary* visas from among the broad set discussed above; such visitors include employees of foreign concerns (such as foreign correspondents and automobile plant managers), members of foreign trade delegations, employees of international organizations (such as the World Bank), and foreign students. Others of the visitors are deportable aliens. Obviously, lack of information on legal status is more serious for some origín countries than for others. The problem would appear to be severe for Mexico, as Mexico probably has substantial contingents of all three main legal types—permanent resident aliens, nonimmigrants, undocumented migrants—and estimated characteristics do not accurately describe any of them.

The lack of information on legal status makes it impossible to estimate naturalization rates or to interpret unambiguously shifts in migrant characteristics. An increase or decrease in average age or schooling or earnings might merely be the result of changes in the legal-status composition of the migrants. For example, even if the schooling and earnings of newly-admitted permanent resident aliens remained the same, a shift upward in intracompany transferees would produce an increase in average earnings while a shift upward in undocumented migrants would produce the opposite.

It should also be noted that citizenship, too, is not unambiguous in most data sets and in the decennial censuses. The rightmost column of Table 14 reports the imputed citizenship at birth for the same combinations of birthplace and parental citizenship for which actual citizenship at birth is reported. As shown, there are two classes of persons whose imputed birth-citizenship differs from actual birth-citizenship: (i) persons born in the United States who are not subject to U.S. jurisdiction and hence are not birth-citizens; and (ii) persons born abroad to one U.S. citizen parent who does not meet the requirements for transmitting U.S. citizenship.

Moreover, the 1970 and 1980 censuses followed a practice that may have resulted in the citizenship misclassification of persons born in the United States to mothers living abroad. Mexicans and Canadians living in border areas would be most affected by this misclassification. Briefly, the census question on nativity instructed, “Print the state where this person’s mother was living when this person was born. Do not give the location of the hospital unless the mother’s home and the hospital were in the same state.” If the instruction was followed, then it was

impossible to correctly answer the next question, on citizenship. Thus, the 1970 and 1980 censuses contain subsets of Mexico-raised U.S. birth-citizens who are misclassified as naturalized U.S. citizens.

Cross-Sectional Nature of Census Data

Because the census data are cross-sectional, studies based on them are subject to two important sets of biases: those arising from emigration selectivity and those arising from the confounding of cohort and experience effects.[22]

With respect to the confounding of cohort and experience effects, it is well-known that studies based on cross-sectional data cannot reveal the patterns of dynamic processes and cannot disentangle age, period, and cohort effects.[23] Thus, when cross-sectional data are used to study migrant behavior, it is impossible to distinguish between the effects of experience in the United States and the effects of factors associated with the immigrant's vintage—that is, with conditions in both the origín country and the United States at the time of entry (including the rules for the selection of immigrants in effect at the time of admission to permanent resident status). For example, as Borjas (1985) notes, in studies of the earnings of immigrants based on cross-sectional data, it is impossible to distinguish between two potential facts: (i) that immigrants improve their earnings as their time in the United States increases, as hypothesized by Chiswick (1978); and (ii) that each successive entry cohort of immigrants has possessed lower earnings potential (possibly as a consequence of the law for the selection of immigrants).

Cross-sectional data have an additional weakness when used to study migration processes. The respondents enumerated in the decennial censuses represent the *survivors* of entry cohorts, cohorts which may be selectively and differentially trimmed by *emigration* decisions (Jasso and Rosenzweig 1982). For example, if immigrants who subsequently emigrate from the United States are non-randomly self-selected and if the selection mechanisms operate differentially across entry cohort and/or country of origín—if, to illustrate, the low achievers from the 1955 entry cohort leave while the high achievers from the 1965 entry cohort leave—then the true adjustment effect cannot be identified. Tracking the progress of an aggregate cohort across successive cross-sectional data bases may thus confound, because of selective emigration, the life-course mobility of an individual with shifts over time in the mixture of sub-sets in the individual's entry cohort. For example, if the high earners in a cohort emigrate, it may appear that the cohort has made no progress when in fact the survivors (initially low earners) have substantially increased their earnings. Biases associated with emigration selectivity may be especially acute for Mexico-born persons, as their emigration may be both high and fluctuating over time.

Coverage and Coverage Change

The validity of inferences concerning changes over time both within and between cohorts of foreign-born persons hinges on changes in coverage. In particular, coverage of undocumented migrants is problematic.

Legal Immigrant Samples Based on Administrative Records of the Immigration and Naturalization Service (INS)

Samples based on administrative records of the INS constitute the major source of information about legal immigrants. These data are of two main types: (i) administrative records covering new legal immigrants and new naturalized citizens; and (ii) surveys of samples drawn from INS records.

INS Administrative Data

Precise information on persons granted permanent resident alien status and on those among them who subsequently naturalize is collected by the U.S. Immigration and Naturalization Service. Public-Use tapes of the New-Immigrant File for the years 1972-1994 are now available (see INS *1994 Statistical Yearbook*, p. 177). Additionally, INS has undertaken to match immigrant and naturalization records for the FY 1977 and 1982 immigrant cohorts; these microdata are also available as public-use tapes. Selected cross-tabulations of data from the New-Immigrant and Naturalization Files are published in the INS *Annual Report* and its successor, the *Statistical Yearbook.*[24]

Strengths of INS Data

The principal advantage of INS data lies in the detailed information on legal status, visa classification, and country-of-origín variables. It is thus possible to study the determinants of naturalization rates, since normally eligibility to naturalize depends on both legal status and length of residence. It is also possible, though with considerably less ease, to study the effects of duration in the United States on employment status and occupation.

The information available in the New-Immigrant File and the Naturalization File includes: (i) personal characteristics, including age, sex, marital status, state of residence (or intended residence, for persons entering to become permanent residents), occupation; (ii) origín-country information, including country of birth, country of last permanent residence, country of chargeability (for numerically limited

Table 14
Actual and Imputed Citizenship at Birth, by Place of Birth and Parental Citizenship

Place of Birth	No. of U.S. Citizen Parents	Citizenship at Birth	
		Actual	Imputed
United States	Two	U.S. citizen	U.S. citizen
United States	One	U.S. citizen	U.S. citizen
United States	Zero—Born subject to U.S. jurisdiction	U.S. citizen	U.S. citizen
United States	Zero—Born not subject to U.S. jurisdiction	Alien	U.S. citizen
Abroad	Two	U.S. citizen	U.S. citizen
Abroad	One—Requirements to transmit citizenship met	U.S. citizen	U.S. citizen
Abroad	One—Requirements to transmit citizenship not met	Alien	U.S. citizen
Abroad	Zero	Alien	Alien

Notes: United States = 50 states, plus outlying territories and possessions to which the United States has extended *jus soli.*

Abroad = Outside the United States.

visas), country of former nationality (for those who naturalize); and (iii) statutory classifications, including the provision of law under which the person became an immigrant, the provision of law under which the person was admitted for nonimmigrant temporary residence prior to immigration (if the person was adjusting from nonimmigrant to immigrant while in the United States), and the category of law under which the person became naturalized, as well as all the relevant dates—of admission to permanent residence, of admission to the prior nonimmigrant residence (if an adjustment of status), and of naturalization.

These data thus provide considerable detail on the circumstances of a given person's becoming an immigrant and acquiring U.S. citizenship. The 1977 Immigrant-Naturalization Cohort and the 1982 Immigrant-Naturalization Cohort, by merging the New-Immigrant and Naturalization Files, make it possible to distinguish important features of a foreign-born person's migration-relevant biography. An examples of such a biographies would be: a person who entered the

United States as a nonimmigrant with a foreign-student visa in 1972, married a U.S. citizen, becoming an immigrant as the spouse of a U.S. citizen in 1977, naturalized in 1987, reporting marital status as divorced.

Deficiencies of INS Data

The INS data have two important shortcomings—missing relevant information and limited longitudinality.

Missing Relevant Information. Important information relevant to the migration process is missing from the INS data. These data do not contain information on earnings, education, family and household structure, or language; in addition, information on occupation obtained from the New-Immigrant file is problematic, at least for persons who are (i) entering to become permanent residents (as opposed to persons adjusting status in the United States), and (ii) entering without labor certification.

The missing information may be regarded as being of three types. The first type consists of relevant attributes and characteristics of *individual* immigrants; this category might comprise information on language, schooling, earnings, and the like. The second type consists of information that would identify *family* groups of individual immigrants; for example, in the existing New-Immigrant File it is impossible to link the record of a person admitted as the spouse of an employment-fourth-preference immigrant with the record of the corresponding employment-fourth-preference principal. The third type of missing information is information on the *sponsor.*

Limited Longitudinality. Even when the New-Immigrant and the Naturalization Files are merged, they provide longitudinal information for each entire cohort on only one variable, naturalization. Longitudinal information on other characteristics, such as occupation, marital status, and state of residence, is available only for the sub-set of the cohort who naturalize. Thus, with the exception of naturalization, information is longitudinal only for a self-selected portion of each New-Immigrant cohort.

Surveys of Samples Based on INS Administrative Data

The principal weakness of INS administrative data—the lack of information on schooling, earnings, and other variables—can be overcome by collecting that information from individuals randomly selected from the administrative data. Such

a design loses none of the strengths of designs based on INS administrative record, overcomes the deficiencies, and, when embedded in a longitudinal data collection framework, overcomes as well the problems associated with cross-sectional data, such as emigration selectivity and confounding of cohort and experience effects.

In this report we draw on a special study carried out by the GAO on the immediate-relative immigrants of FY 1985 and on two main INS-based sample surveys. These are the special two-wave survey of the IRCA legalized population, LPS-1 and LPS-2, and the baseline interview data from the New Immigrant Survey Pilot Study.

The GAO Study

As was noted above, INS data do not include information on an immigrant's sponsor. The General Accounting Office assembled a microdata set containing information on the U.S. citizen sponsors of a probability sample of immediate relatives who became permanent resident aliens in FY 1985. The GAO data include information on whether the sponsor was himself/herself an immigrant and on his/her country of birth. If the sponsor was an immigrant, then information is also provided on the date of admission to immigrant status and the date of naturalization. The data thus make it possible to distinguish not only between birth-citizens and naturalized citizens but also, within birth-citizens, between those born in the United States and those born abroad to U.S. citizen parents.

Legalized Population Surveys

The Legalized Population Surveys, LPS-1 and LPS-2, represent two rounds of a longitudinal survey of a sample of persons legalized under Section 245A of the 1986 Immigration Reform and Control Act. These are persons who had lived in the United States continuously since January 1, 1982, had applied to the INS for legalization, and had been granted legalization in the first phase of the IRCA program (i.e., had been granted legal temporary resident status). During the first round, carried out in February-June of 1989, a total of 6,193 persons were interviewed. The second round selected for interview a subset of the initial interviewees; a requirement for participation in the second round was successful admission to legal permanent resident status. Thus, the population covered by LPS data represent a subset of unauthorized migrants who were in the United States in 1989. It is not necessarily representative of the entire unauthorized migrant population either before or after 1982. Nevertheless, the Mexican subset of the LPS sample provides an important complement to other data sources to estimate characteristics of Mexican migrants, and it includes some variables (e.g., on remittance behavior) not available in other data sets.

NIS Pilot Study

To improve the data base on immigrants, a program of comprehensive, multicohort, longitudinal surveys of new legal immigrants to the United States based on probability samples of INS records was recently developed. This program—the New Immigrant Survey—is designed to monitor changes across cohorts, with new samples drawn periodically, and to monitor adaptation over time, interviewing sample members at regular intervals over the life cycle and also obtaining information about and from their children. To test the design, and in particular to assess the cost-effectiveness of alternative methods of locating and tracking immigrants—with the aim of maximizing both initial and longitudinal response rates—a pilot study is being carried out. The pilot study includes a baseline interview and follow-up interviews over the course of a year. The sample is a probability sample drawn from among the set of persons who became new permanent resident aliens during July and August of 1996. In this report we draw on preliminary results from the baseline interview of the pilot study, which collected information on schooling, English language skill, labor force participation, and earnings both in the United States and abroad.

Farmworker Surveys

UC-EDD Farmworker Survey (1985)

The UC-EDD Survey of California Farm Workers was carried out by the University of California, Davis (UC) and the California Employment Development Department in Sacramento (EDD) in August 1983. The sample includes 554 male farm workers in 37 counties; workers in all crops and production-related activities were interviewed in each survey area. The survey was designed to obtain as representative a statewide sample of farm workers as possible, given the well-documented difficulties inherent in studying this population. The data provide information on farm worker human capital and other sociodemographic characteristics, including immigration status and country of origín; on the type of work and commodity in which farm workers were employed at the time of the interview; and on farm worker earnings. Just over 80 percent of all farm workers in the survey were Mexican-born, and 29 percent were undocumented.

National Agricultural Worker Survey (NAWS)

The National Agricultural Workers Survey (NAWS) was carried out in response to the legislative requirement under IRCA that the Secretaries of Agriculture and Labor determine annually if there is a shortage of Seasonal Agricultural Service

(SAS) workers. The NAWS collects comprehensive job history information on SAS workers to estimate fluctuations in the labor supply. It also gathers sociodemographic and earnings data, similar in most respects to the UC-EDD survey. Only farm workers employed in SAS labor are interviewed for the NAWS. More than 2,000 such workers were interviewed in fiscal year 1990. Unfortunately, the NAWS data have not been made available to us for analysis; only tabulations already carried out and published by DOL may be used.

Notes

1. La Encuesta Nacional de la Dinámica Demográfica (ENADID) representa el acercamiento macrosocial más importante y completo al comportamiento demográfico en México. Integra los tres aspectos de la dinámica demográfica (la fecundidad, la mortalidad y la migración). Es el primer estudio de carácter nacional, que cubre prácticamente todas las zonas del país. Para el tema que nos ocupa, comprende las siguientes unidades de análisis : viviendas, miembros nacionales y extranjeros de esas viviendas, residentes habituales de las viviendas y personas que se fueron a vivir a otro país, de 1987 hasta la fecha de la encuesta.

2. Hicimos algunos cambios a la regionalización presentada en San Diego, con la finalidad de tomar en cuenta las características de las zonas expulsoras y la historia de la participación de cada entidad en la migración.

3. Consideramos que era más adecuado situar a Colima en esta región por su ubicación geográfica y porque aunque en relación al conjunto de migrantes el peso de este estado es muy pequeño, esto se debe a su reducida dimensión, ya que sólo representa el 0.53% de la población nacional, según el conteo poblacional de 1995. Sin embargo, los migrantes constituían el (5.68%) de su población residente, según la ENADID; lo que significa que ocupaba el cuarto lugar, después de Michoacán, Zacatecas, y Durango.

4. La participación de Baja California Sur es mínima, ya que únicamente aporta el 0.2% de los migrantes (que representan, al interior de la entidad, el 0.95% de su población residente), sin embargo, consideramos que ésa era la mejor forma de ubicarla.

5. De acuerdo al documento presentado en San Diego, Zacatecas y San Luis Potosí formaban parte de la región I. Sin embargo, decidimos cambiarlos para dejar únicamente los estados donde la recurrencia de la migración era más constante.

6. Anteriormente, Puebla formaba parte de la región del Valle de México, sin embargo, tomando en cuenta los estudios en la zona se decidió que resultaba más adecuado incorporarlo a la región V debido a que una parte importante de sus migrantes proviene de la región colindante con los estados de Guerrero y Oaxaca, conocida como la Mixteca.

7. Dado el escaso número de migrantes provenientes de esta región, en este documento se omitirá el análisis de su comportamiento.

8. Aunque la información obtenida por este medio es limitada, principalmente en la EMIF.

9. Ver el apéndice metodológico elaborado por el Consejo Nacional de Migración.

10. La medición de los flujos migratorios no puede limitarse a una sola dirección, ello sería equivalente a considerar que los mexicanos al ingresar a los Estados Unidos cambian en forma definitiva su lugar de residencia y rompen con los vínculos familiares y sociales que los hacen regresar periódicamente.

11. Una unidad en tránsito, puede pasar de un flujo a otro.

12. Flujo Sur-Norte: designa al desplazamiento proveniente de cualquier parte de la República y que se concentra en las ciudades de la zona fronteriza del norte de México, ya sea para permanecer en ellas o internarse en los Estados Unidos.

Flujo Norte-Sur: designa a desplazamientos que se dirigen hacia el sur de la frontera norte de México, ya sea porque provienen de los Estados Unidos o de alguna localidad fronteriza.

Será considerado como un tercer flujo al conjunto de deportados por las autoridades migratorias norteamericanas.

Cada uno de los flujos se divide en uno o más subconjuntos, mismos que identificamos como subpoblaciones de análisis.

13. En adelante, para realizar comparaciones entre las subpoblaciones se tomarán las características que presentan en conjunto los deportados.

14. En el diseño metodológico de la EMIF, por cuestiones operativas que fueron probadas a escala en la ciudad de Tijuana y porque algunos movimientos migratorios son demasiado lentos, esporádicos o no tienen puntos específicos de paso-observación, algunas unidades que participan en el flujo migratorio internacional quedan fuera de la metodología propuesta. Tal es el caso de los migrantes locales, transmigrantes o *conmuters, visa abusers* o la migración legal.

15. Algunos de los criterios considerados en el establecimiento de estas regiones fueron: a) la infraestructura de vías de comunicación, toda vez que las rutas que siguen los migrantes no se alejan de la infraestructura existente y b) las localidades o regiones de origen y destino de los migrantes porque se estima que las rutas de los migrantes siguen una lógica que se establece gracias al mercado laboral y a la existencia de redes sociales y familiares, tanto en las zonas de salida como en las de llegada.

16. El criterio principal fue que en ellas se ubican las direcciones regionales de El COLEF que cuentan con la infraestructura necesaria para la operación del proyecto. Por otra parte se evaluó la facilidad de establecer enlaces con las localidades aledañas a la zona fronteriza y se capitalizó la ventaja de contar con personal adecuado para facilitar el contacto con las autoridades oficiales y el sector privado así como el acceso a las diferentes zonas de muestreo.

17. Los criterios considerados para excluir tales localidades fueron:

a) baja densidad en el flujo migratorio

b) localidades que contaban con flujos de carácter local

c) ubicación inadecuada de algunas localidades para la captación de los flujos

d) excesiva distancia entre las localidades y las coordinaciones regionales

18. En esta sección del documento se considera la información de un trimestre del primer levantamiento, que cubre el período del 14 de diciembre de 1993 al 13 de marzo de 1994.

19. Cruz Piñeiro (1992), afirma que muy ligados a la dinámica de la fuerza de trabajo, se encuentran los procesos migratorios; de hecho, gran parte de las tendencias características de la fuerza de trabajo y su inserción laboral en la frontera norte explican y son explicadas a la vez, en función de las características y magnitudes de los flujos migratorios hacia la región. En concreto, una primera aproximación señala que los migrantes constituyen el 70% de la PEA en Tijuana, el 50% en Nuevo Laredo y el 34% en Ciudad Juárez.

20. Si bien es cierto que en la sección del documento destinada a la descripción de las variables a ser consideradas se aclaró la pertinencia de utilizar el tipo de localidad de residencia para llevar a cabo los tabulados básicos, la información obtenida para la variable sexo se incorpora como una característica general.

21. See Shryock and Siegel (1975, pp. 578-580), Keely and Kraly (1978, pp. 270-271), Warren and Peck (1980, pp. 79-80), and Jasso and Rosenzweig (1982; 1986a; 1986b).

22. For fuller discussion of the biases associated with the use of cross-sectional data to study migration phenomena, see Greenwood and McDowell (1986) and the references cited therein.

23. For recent examination of this large literature, see Hobcraft et al. (1982) and Jasso (1985).

24. The *Annual Report of the Immigration and Naturalization Service* published annual data for many of the series of interest from 1943 through 1977 and the *Statistical Yearbook of the Immigration and Naturalization Service* since 1978. Both have included several historical time series. Additional historical time series are collected in U.S. Bureau of the Census, *Historical Statistics of the United States: Colonial Times to 1970*.

Table 3
Top Five States of Residence at Admission, with Percent Distributions at Admission and at Naturalization: FY 1977 and 1982 Cohorts

State	FY 1977		FY 1982	
	Men	Women	Men	Women
A. Intended State of Residence at Admission, All Immigrants				
Arizona	3.70	3.48	3.46	4.10
California	48.13	49.76	34.96	38.07
Illinois	10.41	9.84	8.63	6.28
New Mexico	1.91	1.76	2.26	1.96
Texas	24.91	27.50	37.00	40.82
B. Intended State of Residence at Admission, Immigrants Who Later Naturalized				
Arizona	3.42	4.82	2.95	4.86
California	42.38	42.53	35.14	37.02
Illinois	14.35	13.25	17.20	8.87
New Mexico	1.42	2.10	1.80	2.12
Texas	22.71	26.20	27.04	32.70
C. Naturalized Immigrants				
Arizona	3.52	5.56	3.20	5.21
California	41.25	40.71	34.28	36.29
Illinois	12.72	11.51	16.30	9.06
New Mexico	1.08	2.13	1.43	1.62
Texas	24.05	28.10	25.92	31.12

Table 4
Age Distribution, Legal Immigrants: Fiscal Years 1971, 1977, 1982, 1994

Subset	Summary Characteristics					
	Mean	S.D.	Q(.25)	Q(.5)	Q(.75)	Maximum
A. FY 1971 Legal Immigrants (N = 370,478)						
Men born in Mexico	20.97	14.06	13	18	27	69
Men born elsewhere	26.32	15.44	15	27	34	95
Women born in Mexico	21.05	16.39	9	18	29	74
Women born elsewhere	26.59	15.82	17	25	35	90
B. FY 1977 Legal Immigrants (N = 462,315)						
Men born in Mexico	22.58	13.19	14	23	29	98
Men born elsewhere	28.86	17.76	16	27	39	99
Women born in Mexico	23.26	14.94	13	23	31	95
Women born elsewhere	30.55	18.53	18	27	41	99
C. FY 1982 Legal Immigrants (N = 594,131)						
Men born in Mexico	23.74	12.26	17	24	29	98
Men born elsewhere	26.75	16.27	15	25	35	98
Women born in Mexico	24.56	15.12	14	23	32	95
Women born elsewhere	28.37	17.48	16	26	37	98
D. FY 1994 Legal Immigrants (N = 804,416)						
Men born in Mexico	20.59	14.06	11	18	25	95
excl. legalization dep.	23.38	15.19	13	20	28	95
Men born elsewhere	30.10	17.66	17	29	40	99
Women born in Mexico	25.82	15.49	14	24	34	98
excl. legalization dep.	27.32	16.22	16	25	36	98
Women born elsewhere	31.58	18.01	19	29	42	99

Notes: Figures for 1977, 1982, and 1994 are calculated from the INS microdata public use files; 1971 figures are calculated from a one-in-one-hundred sample of the immigrant cohort. Cohort sizes refer to the complete cohorts; missing data on sex or age may slightly reduce the size of the populations/sample on which calculations are based. Data for 1982 include 2,300 Silva case adjustments. Data for 1994 exclude 6,022 IRCA-legalized persons but includes 34,074 legalization dependents. The minimum age observed in all groups in all years is zero, which represents infants less than one year old. Q denotes the quantile function; thus, Q(.25) denotes the 25th percentile and Q(.5) denotes the median.

Table 5
Age Distribution, FY 1994 Legal Immigrants, by Visa Category

Subset	Summary Characteristics						
	Mean	S.D.	Q(.25)	Q(.5)	Q(.75)	Maximum	N
A. Employment Visas, Except Third Preference "Other Workers" and Fourth Preference: Principals							
Men born in Mexico	32.62	8.47	27	31	38	68	641

Table 8
Years of Schooling Completed Among Mexico-born and All Immigrants Aged 25 Years and Over at Admission, by Visa Class: NIS 1996 Cohort

	All Immigrants		Born in Mexico	
Visa Class	Mean	S.D.	Mean	S.D.
Spouse of U.S. citizen	13.6	4.6	12.7	4.9
Parent of (adult) U.S. citizen	7.5	5.1	4.5	4.3
Sibling, principal and spouse	13.4	5.4	7.5	2.1
Employment, principal and spouse	16.1	4.3	16.0	6.1
Refugee/asylee, principal and spouse	13.1	4	–	–
Diversity, principal and spouse	14.5	3.3	–	–
Other	11.1	4.7	7.3	3.9
All Immigrants 25 and over	12.7	5.1	8.9	5.5

Note: Figures are for all immigrants in the NIS 1996 cohort (July and August 1996) who were aged 25 years and over at admission to permanent residence.

Table 9
English Language Skill Among Immigrants Born in Mexico Aged 18 Years and Over at Admission, by Whether They Ever Entered the United States Without Inspection (EWI): NIS 1996 Cohort

English Language Proficiency	All	No EWI Experience	Some EWI Experience
Speaks English “very well”	9.1	12.9	5.6
Speaks English “fairly well”	9.7	16.7	5.6
Speaks English “average or so-so”	32.9	26.2	38.1
Speaks English “not very well”	17.9	13.2	21.4
Speaks English “not well at all”	30.3	30.9	29.3

Note: Respondents classified as having EWI experience met at least one of two criteria: (i) their first trip to the United States was without legal documents, or (ii) adjustment to permanent residence was from an EWI status.

Table 10
Sex and Citizenship Type of the U.S. Citizen Sponsors of Immediate Relatives, for All Immediate Relatives and Those Born in Mexico: Evidence from the GAO FY 1985 Immediate-relative Immigrants File

Sponsor's Citizenship Type	Spouses	Own Children	Adopted Children	Parents
A. All Immediate-Relative Immigrants				
Birth-Citizen, Born in U.S.	76.28	52.57	97.89	2.91
Birth-Citizen, Born Abroad to U.S. Parent(s)	4.02	12.64	0	1.65
Birth-Citizen, Place of Birth Not Known	0.18	0	0	0
Naturalized Immigrant	19.52	34.79	2.92	95.44
Total Sponsored Immigrants	124,093	25,778	9,286	38,986
B. Immediate-Relative Immigrants Born in Mexico				
Birth-Citizen, Born in U.S.	74.26	48.48	0	6.67
Birth-Citizen, Born Abroad to U.S. Parent(s)	2.94	24.24	0	6.67
Birth-Citizen, Place of Birth Not Known	0.74	0	0	0
Naturalized Immigrant	22.06	27.27	0	86.67
Total Sponsored Immigrants	28,957	6,425	137	2,464
C. Immediate-Relative Immigrants Born in Mexico, Sponsored by U.S. Men				
Birth-Citizen, Born in U.S.	73.17	48.00	0	11.11
Birth-Citizen, Born Abroad to U.S. Parent(s)	4.88	20.00	0	0
Birth-Citizen, Place of Birth Not Known	2.44	0	0	0
Naturalized Immigrant	19.51	32.00	0	88.89
Total Sponsored Immigrants	8,730	4,868	NA	1,479
D. Immediate-Relative Immigrants Born in Mexico, Sponsored by U.S. Women				
Birth-Citizen, Born in U.S.	74.74	50.00	0	0
Birth-Citizen, Born Abroad to U.S. Parent(s)	2.11	37.50	0	16.67
Naturalized Immigrant	23.16	12.50	0	83.33
Total Sponsored Immigrants	20,227	1,557	NA	985

Note: All figures are sample estimates except the total numbers of immigrants in Panels A and B. All naturalized-citizen sponsors of Mexico-born immediate relatives were themselves born in Mexico except for 13.64 percent of the women sponsors of spouses, of whom two-thirds were born in Germany and the remaining one-third in Cuba. Of the birth-citizens born abroad who sponsored Mexico-born immediate relatives, all were themselves born in Mexico.

Table 11
Occupational Distributions, Immigrants Born in Mexico, Aged 21–65 at Admission to Permanent Residence: FY 1977, 1982, 1994 Cohorts

Summary Occupation Group	FY 1977 Cohort		FY 1982 Cohort		FY 1994 Cohort

Characteristics of Migrants

Mexico-to-U.S. Migrant Characteristics from Surveys Involving Samples Drawn in Mexico

Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor & Paz Trigueros Legarreta

Características sociodemográficas

Sexo

El 91.82% del total de los migrantes laborales son hombres, lo que representa un índice de masculinidad de 1,122 hombres por cada 100 mujeres. Del flujo sur-norte, la proporción de hombres fue del 96.88%. De éstos el 54.71% se dirigieron a la frontera norte y el 45.29% hacia los Estados Unidos. Las mujeres representan sólo el 3.12%, teniendo el 55.43% como destino la frontera norte.

En el flujo norte-sur, destaca que aproximadamente nueve de cada 10 mujeres procedìan de la frontera norte.

Del total de varones, la mayoría se concentra en el flujo sur-norte (48.44%). Sin embargo si consideramos a las subpoblaciones destaca el hecho de que quienes

Cuadro 1
Migrantes Laborales
Porcentaje Estimado Según Sexo y Subpoblación
(14/Dic/93 al 13/Mar/94)

	Flujo		
	Sur-Norte	Norte-Sur	Deportados
Masculino	48.44	31.64	19.92
Femenino	17.55	57.04	25.40
Indice De Masc.	31.01	6.23	8.81

tienen como destino alguna ciudad de la frontera norte, agrupan el mayor número del total del flujo migratorio laboral, seguidos por los deportados y los procedentes de Estados Unidos.

Destaca que en términos relativos, existe una mayor proporción de mujeres deportadas que hombres.

En el caso de las mujeres, el 57.04% de las que participan en la corriente migratoria se encuentra en el flujo norte-sur, en donde la mitad proviene de la zona fronteriza. Si tomamos el total de mujeres captadas para la población laboral (47,255), el 50.74% procede de alguna ciudad de la frontera.

Grupos de edad

La estructura por edad es característica de las migraciones temporales, y se concentra en aquellas donde se desarrollan las actividades económicas, ya que del flujo sur-norte el 74.48% de los migrantes laborales tienen entre 15 y 34 años y un 73.46% para el flujo norte-sur. Cabe destacar que para los deportados aquellos que se encuentran en estos grupos de edad representan el 86.86%.

Si consideramos los grupos de edad por subpoblación de análisis los más jóvenes (entre 15 y 19 años) se dirigen a la frontera norte y aquellos que se agrupan entre los 25 y 34 años lo hacen hacia los Estados Unidos. Presumiblemente podemos pensar que aquellos que se dirigen a las localidades fronterizas inician su carrera migratoria y aquellos que declaran que se dirigen a los Estados Unidos cuentan con experiencia migratoria de al menos un cruce a la frontera, sobre todo si detectamos que para el flujo norte-sur la mayoría de los que regresan de alguna ciudad de los Estados Unidos tienen entre 25 y 34 años; para el caso de los deportados también la mayor proporción se encuentra entre estas edades.

Escolaridad

En lo que se refiere a la escolaridad[1] de los migrantes laborales los resultados de la encuesta permiten apuntar que la gran mayoría de los entrevistados se concentran en los niveles de primaria y secundaria, estos dos niveles significan el 77.35% del total, siendo más importante el primer nivel ya que reúne casi el cincuenta por ciento de los captados por la EMIF (49.54%).

Se puede destacar que si bien la instrucción formal básica y media es notoria, también lo son los porcentajes de participación de aquellos que declararon niveles medio superior (9.75%) y superior (2.91%) y aún más alta la presencia de los que declararon no contar con algún nivel de escolaridad (9.99%).

Estado civil

Una de las características importantes de los migrantes se asocia con el estado civil y los llamados jefes de hogar. En la discusión de redes familiares y remesas, por mencionar algunos temas relacionados con el fenómeno migratorio, comunmente se asocia el comportamiento de los migrantes con la existencia de una serie de vínculos familiares y extrafamiliares para sustentar la posibilidad de migrar, el envío de parte del ingreso obtenido, la misma decisión de migrar, etc.

De acuerdo con la EMIF, del total del grupo de migrantes laborales la proporción entre solteros y casados es similar (46.27% y 48.45% respectivamente). Es, sin embargo, al interior de los flujos y subpoblaciones donde se apuntan importantes diferencias en la distribución. El grupo de casados es mayoritario en los flujos sur-norte y norte-sur, sólo en el flujo de deportados los solteros son mayoría (62.45%) y probablemente esté asociado con el hecho de que el 51.03% de éstos tienen entre 15 y 24 años de edad.

Considerando las subpoblaciones, la proporción entre solteros y casados de quienes se dirigen a alguna ciudad de la frontera norte, es prácticamente la misma. Sin embargo entre los que regresan de alguna de estas ciudades o quienes son devueltos por la patrulla fronteriza predominan los solteros.

Jefes de hogar

Respecto a la posición al interior del hogar, en el período bajo consideración se encuentra que la mayoría de los migrantes laborales eran jefes de familia (55.05%). En la distribución por subpoblación es notable el caso de los que tienen como destino los Estados Unidos (SEU) en que además declararon ser cabezas de familia (70.99%). Entre los procedentes de la frontera norte (FNS) y deportados (DEP) quienes no son jefes de familia, es decir que pueden ser hijos, esposos(as), otros familiares o amistades son más numerosos (54.25 y 56.43% respectivamente).

Localidad de residencia

El patrón de origen-destino es uno de los que más cuidado merecen, pues los efectos de los movimientos migratorios sobre los referentes geográficos son de notable trascendencia. A partir de los resultados de la encuesta es posible determinar las características generales de los lugares de origen[2] de los migrantes laborales. En primer lugar se puede apuntar que la encuesta ha captado en su mayoría migrantes cuyo origen es urbano (58.49% frente a un 41.51% que declaró provenir de localidades no urbanas). Considerando los flujos se tiene una mayor proporción de migrantes laborales que residen en localidades urbanas, para el flujo sur-norte la proporción es de 53.32%, para el norte-sur 60.35% y para deportados 67.63%.

Estado de residencia

Para referirnos a la distribución de las entidades de origen de los migrantes laborales han sido identificados los estados más importantes para cada flujo y subpoblación. De acuerdo al cuadro resumen, para el flujo con dirección sur-norte, es decir aquellos que declararon dirigirse hacia alguna ciudad en la frontera norte o bien hacia alguna ciudad en los Estados Unidos, los migrantes provenían de alguna de las siguientes entidades por orden de importancia: Michoacán (10.14%), Guanajuato (9.65%), Sinaloa (8.97%), Coahuila (7.63%) y Jalisco (7.22%).

Cabe destacar a los migrantes de los estados de Guanajuato y Michoacán en la población que se dirige hacia los Estados Unidos pues ellos aportan el 16.64% y el 16.49% respectivamente de esta subpoblación.

En el caso de las subpoblaciones que conforman el flujo norte-sur, los estados de mayor importancia son: Coahuila (10.7%), Guanajuato (9.79%), San Luis Potosí (7.21%), Durango (6.52%), Oaxaca (5.90%), Veracruz (5.73%), Sonora (5.47%), Nuevo León (5.08%), Chihuahua (4.80%) y Michoacán (4.72%).

Para el caso de los deportados, los migrantes de Baja California (10.86%), Michoacán (10.08%) y Tamaulipas (8.08%) son los que tienen una mayor importancia.

Características socioeconómicas

Condición laboral y sector de actividad en el lugar de residencia

En el flujo migratorio sur- norte el 75.21% manifestó haber trabajado en su lugar de residencia. De los que se dirigieron a la frontera norte y a los Estados Unidos, el 79.59% y el 69.91%, respectivamente, declararon que tenían trabajo en su lugar de residencia. La proporción es similar en los flujos norte-sur y deportados.

De los migrantes laborales que participaron en el flujo sur-norte el 22.50% manifestó no haber trabajado en su lugar de residencia, el 31.91% declaró haber trabajado en actividades agrícolas, el 22.68% en actividades industriales y el 21.74% en comercio y servicios.

De aquellos que declararon no haber trabajado y los que lo hicieron en el sector agrícola, más del cincuenta por ciento (53.25 y 54.43%, respectivamente) tuvo como destino los Estados Unidos.

La frontera norte se constituyó en el destino de la mayor proporción de los migrantes laborales que, en su lugar de residencia, trabajaron en los sectores industrial y comercio y servicios (60.19 y 72.87%, respectivamente).

Haciendo referencia a los migrantes procedentes del norte, se observa que aquellos que trabajaron en su lugar de residencia antes de su ingreso a los Estados Unidos presentan un patrón por sector de actividad similar al de los que se desplazan en sentido sur-norte; es decir, la mayor proporción trabajó en actividades agrícolas (30.05%), seguido por el sector industrial (24.13%) y en una menor proporción en el sector servicios y comercio (23.99%).

Cabe señalar que la proporción de migrantes que no trabajó en su lugar de residencia es mayor a la proporción de aquellos que trabajaron en la industria o el comercio, dado que el 27.95% del total de migrantes manifestó no haber trabajado antes de iniciar su desplazamiento hacia el norte.

De los migrantes procedentes de los Estados Unidos, el 38.99% manifestó haber trabajado en el sector agrícola , el 22.02% en la industria y el 11.04% en comercio y servicios. El restante 27.95% declaró no haber trabajado en su lugar de residencia antes de su ingreso a ese país.

Para el flujo de deportados, el sector industrial concentra una mayor proporción, ya que del total del flujo el 30.89% trabajó en ese sector. Por otra parte, los que no trabajaron en su lugar de residencia tienen una menor proporción relativa, puesto que sólo el 18.64% de ellos declaró no haber trabajado 30 días antes de iniciar su viaje hacia los Estados Unidos.

Estado de residencia y localidad de destino en la Frontera Norte

Al analizar la distribución de porcentajes de migrantes laborales que se desplazaron del sur hacia la frontera norte, la zona[3] de Tijuana concentró el 44.93%, Cd. Juárez el 25.43%, Piedras Negras el 8.73%, Matamoros el 7.52%, Nogales el 6.80%, Mexicali el 3.97% y Nuevo Laredo el 2.62%.

El mayor número de migrantes que llegaron a la zona de Tijuana procedía de los estados de Sinaloa (25.10%), Oaxaca (14.85%) y Michoacán (9.55%). Cabe hacer la aclaración que a excepción del estado de Sonora que aporta el 4.15%,

ningún otro estado fronterizo contribuye con migración laboral hacia dicha zona. Nogales, también presenta una alta dispersión en los estados de procedencia, sin embargo, son las mismas localidades de Sonora las que contribuyen con la mayor proporción (35.30%). Esta zona atrae en mayor medida migrantes procedentes de Sinaloa (19.10%), el Distrito Federal (7.64%) y Michoacán (6.38%). A diferencia de la zona de Tijuana, la zona de Nogales concentra población migrante de otros estados fronterizos.

Los estados que participan en mayor medida con migración laboral hacia la zona de Cd. Juárez son: las localidades no fronterizas del estado de Chihuahua[4] con el 27.74%, Durango con el 24.75%, Zacatecas con el 13.27% y Aguascalientes con el 7.46%.

El estado de Sonora contribuye con el 46.0% del total de los migrantes que tuvieron como destino la zona de Mexicali, seguido por los estados de Guanajuato (15.89%), Sinaloa (14.28%) y Oaxaca (13.18%), es decir, cuatro estados concentraron el 89.35% del total de los migrantes laborales que se desplazaron en este período a la zona de Mexicali.

La zona de Piedras Negras capta la mayor parte de migrantes de las localidades no fronterizas de Coahuila[5] (73.90%), y en una menor proporción de Nuevo León (13.16%).

De los migrantes que se desplazaron a la zona de Matamoros, el 36.35% proviene de localidades no fronterizas del estado de Tamaulipas, el 18.32% del estado de México, el 14.35% de Veracruz, el 13.56% de San Luis Potosí y el 10.31% de Nuevo León.

A la zona de Nuevo Laredo, llegan migrantes procedentes, en orden de importancia, de los estados de Jalisco (20.17%), Nuevo León (17.55%), Guerrero (9.46%), Guanajuato (8.93%), Veracruz (8.56%), Coahuila (8.46%) y Oaxaca con el 7.85%.

Localidad fronteriza de mayor estancia y estado al que se dirigen

En el flujo norte-sur, la distribución porcentual de los migrantes laborales procedentes de la frontera norte con destino al sur[6], se presenta de la siguiente manera: el 23.50% provenía de Matamoros, el 16.92% de Tijuana, el 16.18% de Juárez, el 12.51% de Piedras Negras, el 10.60% de Nogales, el 10.57% de Mexicali y el 7.92% de la zona de Nuevo Laredo.

De los migrantes procedentes de Matamoros, un 26.11% se dirigía a las localidades no fronterizas del estado de Tamaulipas, 21.53% a San Luis Potosí, 20.09% a Veracruz, 9.39% a Nuevo León y el 8.91% a Guanajuato y en menor proporción al estado de México (5.78%) y Guerrero (2.86%).

El 66.61% del total de migrantes procedentes de Piedras Negras se dirigía hacia localidades no fronterizas del estado de Chiuhahua, el 11.63% a Nuevo León, el 7.95% al estado de México. Tres estados concentran el 86.19% del total de migrantes procedentes de la zona fronteriza de Piedras Negras.

Los migrantes que proceden de Tijuana presentan una mayor dispersión hacia los estados de destino en el interior de la república, siendo los más significativos el estado de Sonora (11.09%), Oaxaca (10.60%), Sinaloa (8.90%), Puebla (8.84%), Nayarit (8.54%) y Coahuila con el 7.36%.

De manera similar, los procedentes de Nogales presentan una dispersión hacia los lugares de destino con la diferencia que, el 55.90% se dirigía hacia las localidades no fronterizas de Sonora y el 18.96% hacia Sinaloa, es decir, el 74.86% del total de migrantes que provenían de la zona de Nogales se dirigía hacia las mismas localidades de Sonora y al estado de Sinaloa.

Los provenientes de la zona Juárez se dirigían en mayor proporción hacia las localidades no fronterizas de Chiuhahua (37.35%), seguidos, en orden de importancia, por los que se desplazaban hacia Coahuila (21.33%), Durango (18.02%) y Zacatecas (7.46%).

Del total de migrantes que proceden de la zona de Mexicali, el 42.09% se dirigía hacia Oaxaca, el 13.61% a Sonora, el 12.92% a Sinaloa y en menor proporción hacia Nayarit (5.70%), Jalisco (3.67%), el Distrito Federal (3.57%) y Guanajuato (3.23%).

Los estados de San Luis Potosí, Durango, Jalisco, Tamaulipas, Coahuila y Veracruz concentran las mayores proporciones de los migrantes procedentes de la zona de Nuevo Laredo, ya que a ellos se dirigían el 14.89, 12.84, 11.76 , 10.34, 9.51 y 9.35%, respectivamente.

Ciudad fronteriza de cruce

Las ciudades de preferencia para cruzar hacia los Estados Unidos son Tijuana (19.01%), Cd. Juárez (14.59%) y Nuevo Laredo (11.88%). Tomando relevancia otras ciudades de Tamaulipas ya que concentran el 24.25%. Cabe resaltar que es Tijuana la que concentra un mayor número de deportaciones, puesto que el 50.63% de devoluciones se realiza por esta ciudad.

Posesión de documentos para cruzar y/o trabajar en los Estados Unidos

En el flujo norte-sur, el 54.63% manifestó tener documentos para cruzar hacia los Estados Unidos. Esto deja ver la alta proporción de migrantes laborales indocumentados, toda vez que el 98.38% de los migrantes deportados no poseen

ese documento. Si examinamos la posesión de documentos para trabajar, el 54.93% de los migrantes procedentes del norte si cuenta con él.

Texas y California son los estados donde la población migrante declara un mayor tiempo de estancia. El 80.60% de los migrantes laborales procedentes de los Estados Unidos declaró haber trabajado en ese país, es decir, de 75,661 migrantes, 60.980 trabajaron.

Notes

1. En la EMIF para la variable escolaridad se propone una agrupación para los niveles de secundaria, preparatoria y profesional en la que están incluidos otros niveles de instrucción. Cuando se hace referencia al nivel de escolaridad para secundaria estarán incluidos los que declararon haber terminado ese nivel y aquellos que concluyeron estudios técnicos con primaria; para el caso de preparatoria se hace referencia a los técnicos con secundaria y en el nivel profesional también se incluyó la Normal.

2. Como lugar de origen nos referimos en este momento al estado o tipo de localidad de residencia.

3. Se ha incorporado la utilización del término *zona* para hacer referencia a las localidades que están agrupadas en cada coordinación regional, por lo que no se hace referencia a una agrupación distinta a la utilizada a lo largo del texto, amén de evitar que el tamaño de muestra no sea representativo. Cada una de estas zonas está conformada por las siguientes localidades:

a) La zona de Tijuana comprende las localidades de Tijuana y Tecate.

b) La zona de Juárez comprende las localidades de Cd. Juárez, Porfirio Parra, Rodrigo M. Quevedo y El Porvenir.

c) La zona de Piedras Negras comprende las localidades de Piedras Negras y Cd. Acuña.

d) La zona de Matamoros comprende las localidades de Matamoros, Reynosa, Camargo y Miguel Alemán.

e) La zona de Nogales comprende la localidad de Nogales.

f) La zona de Mexicali comprende las localidades de Mexicali y San Luis Río Colorado.

g) La zona de Nuevo Laredo comprende la localidad de Nuevo Laredo.

4. Se sabe que son localidades no fronterizas toda vez que el migrante ha declarado no residir en la localidad donde se realiza la entrevista.

5. Aplica la razón expresada en la nota anterior.

6. El destino pueden ser las localidades no fronterizas de los estados del norte o cualquier estado del interior de la república mexicana

Characteristics of Migrants

Mexico-To-U.S. Migrant Characteristics from Mexican Data Sources

Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor & Paz Trigueros Legarreta

Revisión de la bibliografía escrita por autores mexicanos antes de la aprobación de IRCA; sobre las características demográficas, sociales y económicas de los migrantes mexicanos a Estados Unidos

Características metodológicas

Los materiales revisados son de dos tipos: los que estudian el fenómeno migratorio desde una perspectiva macrosocial, tratando de conocer las características generales de los migrantes mexicanos, y aquéllas que prefieren analizar la problemática a partir de estudios de caso, ya sea en alguna o algunas comunidades expulsoras o en una región.

Desde una perspectiva histórica, los primeros trabajos sobre el tema son los de Manuel Gamio (1930 y 1969), Alfonso Fabila (1932) y Enrique Santibáñez (1930), fueron excepciones en esos tiempos.

Es probable que el interés de estos autores por el tema esté vinculado a la ola antimexicana que se desató en el vecino país del norte debido a la crisis económica de 1929. El más importante de ellos, es el de Manuel Gamio (1930 y 1969), ya que hizo un concienzudo estudio sobre el fenómeno migratorio, de 1926 a 1929, utilizando una gran variedad de fuentes como son los censos de Estados Unidos y de México, la información de la Secretaría de Gobernación respecto a las entradas y salidas de mexicanos, y la del gobierno norteamericano sobre las "money orders" destinadas a México, entrevistas en profundidad, etc.

Los trabajos de los otros dos autores, aunque de menor valor científico, aportan importante información para una época en la que poco se investigó al respecto. Fabila, etnólogo mexicano, escribió sobre sus observaciones en Estados Unidos con la finalidad de prevenir a los mexicanos que se interesaban en ir a trabajar a ese país, motivo por el cual sus textos describen las pésimas condiciones de vida de sus connacionales residentes en Estados Unidos y los malos tratos a los que estaban sujetos.

Santibáñez, periodista y funcionario consular, publicó una serie de artículos en el diario *Excélsior*, que fueron reunidos posteriormente en un libro. Utilizó como técnicas: observaciones personales, encuestas efectuadas por él y sus colaboradores "con una gran cantidad de inmigrantes mexicanos", noticias periodísticas, estadísticas, disposiciones oficiales y datos históricos.

En los años siguientes, sobre todo en la década de los 1950s se publicaron varios libros, de carácter más bien descriptivo, enfocados, principalmente, al importante fenómeno del bracerismo, que atrajo a tantos mexicanos, a partir del convenio firmado por los gobiernos de México y Estados Unidos en 1942. Moisés González Navarro (1954) lo estudia desde una perspectiva histórica y otros como Luis Fernández del Campo (1942), Miguel Calderón (1952), Ignacio García Téllez (1955), José Lázaro Salinas (1955) y Jesús Topete (1961),[1] enfocan de manera un tanto descriptiva distintos aspectos de la problemática económica y social de los braceros mexicanos.

A fines de los1960s, a raíz de la terminación del Programa Barcero en 1964, que dio lugar al auge de la migración indocumentada, se inicia otra etapa en la que participa como figura principal Jorge Bustamante. Desde sus primeros estudios con Julián Samora y Cárdenas, comienza a plantear la necesidad de estudiar el problema de una manera más científica. En el libro *Los Mojados (The Wetback Story* (1971)), los autores mencionados, refieren los resultados de su investigación, realizada en tres centros de detención norteamericanos en 1968-1970, donde aplicaron cuestionarios a 493 hombres de aproximadamente mil que había en esos momentos; y realizaron varias entrevistas en profundidad (Samora, 1971: 67-68; Bustamante, 1976 y Bustamante 1979).

En una siguiente etapa, Bustamante, con un importante equipo de investigadores entre los que estaban Manuel García y Griego, Rodolfo Corona y Carlos y César

Zazueta, emprenden una investigación en el el Centro Nacional de Información y Estadísticas del Trabajo de la Secretaría del Trabajo y Previsión Social (CENIET); que culmina con la Encuesta Nacional de Emigración a la Frontera Norte del País y a los Estados Unidos (ENEFNEU), aplicada entre diciembre de 1978 y enero de 1979. Uno de sus principales méritos fue el de tratar de conocer la dimensión y las principales características de los migrantes, de manera directa, a nivel nacional, a partir de una muestra seleccionada probabilísticamente, que abarcaba a todo el país (CENIET, 1982: 57). Abarcó 62,500 viviendas en 115 localidades, seleccionadas probabilísticamente, lo que permitió captar información de aproximadamente 300,000 individuos.

La encuesta proporcionó una amplia información que permitió tener un mayor conocimiento de las características socio-económicas del fenómeno, estimar su dimensión y determinar las principales áreas de expulsión.

Sin embargo, la necesidad de abarcar un universo tan amplio, restringía la posibilidad de profundizar sobre aspectos importantes de la migración. Uno de ellos, que además estaba adquiriendo auge entre los investigadores sociales, era el de la unidad doméstica de donde procedía el migrante y su papel en este fenómeno.

Así surgieron una serie de investigaciones en comunidades expulsoras de migrantes internacionales, con un enfoque de tipo antropológico, e inspiradas en el análisis estructural. Podemos señalar entre ellas, la del equipo de la UAM Azcapotzalco, coordinado por James Cockcroft, la de López Castro, la de Alarcón y la de Fonseca y Moreno. Los estudios se realizaron en el estado de Michoacán, tanto en cabeceras municipales, como poblados y ejidos; en zonas de agricultura tradicional y modernizada, donde se aplicaron, encuestas, complementadas con historias de vida. En todas se habla de la poca actividad económica no agrícola en la comunidad o el pueblo, muchas veces debido a la centralización que ha tenido lugar en ciudades como: Zamora, Morelia y Guadalajara. Entre las investigaciones en otras entidades federativas están la de Diez Canedo (1984), quien utilizó la información que recabó trabajando con Wayne Cornelius, en la región de Los Altos de Jalisco; y las de Ortiz (1980), Ornelas (s/f) y Rionda (1983) en Oaxaca. Se trata, en todos los casos, de estudios llevados a cabo a fines de los 1970s o principios de los 1980s.

En general, todos ellos tratan de entender la migración internacional como un proceso histórico, en el que influyen elementos de diversa índole, que propician comportamientos específicos en cada etapa y en cada grupo social, así como transformaciones a través del tiempo (Trigueros; 1994).

Fonseca y Moreno estudiaron el fenómeno migratorio en Jaripo, Michoacán, entre febrero y junio de 1981. Su principal fuente fueron entrevistas abiertas a informantes clave (Barjau; 1982; Fonseca; 1986, y Fonseca y Moreno; 1988).

Alarcón (1988), se basó en una encuesta levantada en la cabecera municipal de Chavinda, Michoacán, que abarcó 200 viviendas e incluyó a todos los individuos varones mayores de 18 años.[2]

López Castro (1986), por su parte estudió la migración desde un poblado llamado Gómez Farías en Tangancícuaro, Michoacán. Su investigación se basó, para el período de 1900 a 1919 en historias orales recogidas en junio y julio de 1983 en Gómez Farías, Francisco J. Múgica y Tierras Blancas, así como en información documental. Para la historia más reciente, utilizó, además, dos encuestas que aplicó entre marzo y octubre de 1983. La primera, a 110 familias con base en un muestreo aleatorio, encabezadas por: 88 de jornaleros, 11 de poseedores, 2 de comerciantes, 9 dedicados a otras actividades.[3] La segunda, a 48 productores seleccionados con una muestra estratificada y que tenía como finalidad obtener datos sobre su unidad productiva, la historia migratoria del productor y su familia y su relación con la introducción a la tecnología.

Cockcroft, et al. (1981) y Trigueros y Rodríguez (1988) con todo el equipo de la UAM, estudiaron una comunidad de ejidatarios cercana a Morelia, llamada La Purísima. Utilizaron censos levantados en las décadas de los 1930s y 1940s; una encuesta aplicada por el grupo en 1981, que abarcó a gran parte de las familias de la comunidad, e historias de vida y entrevistas en profundidad, recogidas también en 1981.

Por otro lado, en 1984 se emprendió un nuevo esfuerzo para estudiar la forma como había evolucionado el fenómeno migratorio a nivel nacional. El Consejo Nacional de Población realizó la Encuesta en la Frontera Norte a Trabajadores Indocumentados devueltos por las autoridades de los Estados Unidos de América (ETIDEU), que se basó en 9,631 entrevistas a migrantes deportados. Incluye a las personas de nacionalidad mexicana de 15 años o más que fueron devueltas entre el 5 y el 16 de diciembre de 1984 en distintos puestos fronterizos. A diferencia de la ENEFNEU, el carácter casual o fortuito, no probabilístico de esta encuesta impide inferir valores cuantitativos de la población objetivo (CONAPO;1986).

A diferencia de las investigaciones anteriores, la de Verduzco (1992), se enfocó al estudio de la migración internacional de origen urbano, en la ciudad de Zamora, donde encuestó a una muestra de 801 trabajadores.

Periodización de la migración internacional mexicana

Primera etapa

Santibáñez (1930: 77) señala que fue a partir de los 1850so cuando tuvieron lugar los primeros desplazamientos de mexicanos a Estados Unidos, y concretamente a Texas, ya incorporada a la Unión Americana. Lentamente surgían y se desarrollaban

poblaciones a lo largo de la margen del Río Bravo o cercanas a él. Pasaban el río sin ninguna dificultad y se instalaban, superando con mucho el número de los pobladores de raza sajona. Más adelante, la construcción de los ferrocarriles facilitó la movilización de los mexicanos del centro del país; aunque, según el autor, no llegaban a introducirse más allá de San Antonio.

Entre los fenómenos que propiciaron la gran movilización de mexicanos a Estados Unidos están la Revolución de 1910 y la 1a. Guerra Mundial. La expansión de la industria de guerra y la salida de ciudadanos norteamamericanos (incluyendo mexico-americanos) creó una escasez de fuerza de trabajo. En una amplia gama de actividades los trabajadores en Estados Unidos fueron remplazados por mexicanos. Cuando en 1924 la "National Origins Act" disminuyó considerablemente la immigración de Europa y de otras partes del mundo, México, otra vez fue el gran proveedor de trabajo. (Samora;1971:18).

En muchas de las comunidades analizadas se hace mención a estos primeros desplazamientos. Ochoa (1986) señala que ya en 1872 había michoacanos en Estados Unidos. Desde la fiebre del oro californiano, algunos arrieros de Cotija lograron llegar hasta allá. Sin embargo, parece ser que los primeros migrantes del Bajío Zamorano salieron hasta principios de este siglo (Alarcón y de la Peña, 1989).

Algo semejante ocurrió en Jaripo (Mich.), cuyos vecinos comenzaron a ir a Estados Unidos en la década de los 1920s, aunque hubo quienes fueron desde fines del siglo pasado. Fonseca atribuye el arraigo de esta práctica al éxito que tuvieron los primeros que se aventuraron.

En Chavinda, la migración internacional se inició a principios de siglo, al igual que en Gómez Farías (antes Puentecillas). Aunque no se trataba de una movilización masiva, los hacendados se quejaban de la falta de mano de obra disponible. Aumentó en 1918 debido a la sequía y a las bandas de asaltantes que proliferaron con la Revolución de 1910. López Castro señala que en otros poblados del distrito de Zamora aumentaba esta práctica año tras año: Purépero, Tlazazalca, Chilchota y Tangancícuaro (López Castro, 1986: 36-38; también hace referencia a esta situación Alarcón, 1988).

En la ciudad de Zamora, también hubo quienes migraron durante los primeros años de este siglo, al igual que en los casos señalados, se trataba de un fenómeno marginal, que se extendió durante el período revolucionario y los años que le siguieron, como respuesta a la violencia militar y a la desarticulación económica (Verduzco, 1992).

En Los Altos de Jalisco la situación es semejante. De acuerdo a Alarcón y de la Peña (1989) su historia social en el presente siglo "no puede comprenderse sin hacer referencia a la migración a Estados Unidos." Recuerda que en varias novelas sobre la vida de esa zona a principios de siglo participan "norteños", quienes "juegan un papel de ruptura social y prefiguran la revolución mexicana por su desprecio a las

tradiciones, su rechazo a los trabajos mal remunerados y su altivez ante los patrones y ricos". Diez Canedo (1984), encontró en las comunidades donde hizo su estudio, que la migración tuvo su origen en la época del conflicto cristero (1925-1928).

Resultaba muy caro ir hasta Estados Unidos por las deficientes comunicaciones y porque los ingresos de la mayoría eran muy bajos. Es por eso que algunos autores señalan que entonces viajaban los que pertenecían a familias más acomodadas (Trigueros, 1994). Sin embargo, en el caso de Jaripo, parece ser que los que contaban con más recursos prestaban dinero a otros compañeros para realizar el viaje en grupo.

Por último, López Castro (1986:75-76) habla de la repatriación debida a la crisis de 1929 y señala que, debido a ella y a los temores de los posibles migrantes, la población de Puentecillas tuvo una tasa de crecimiento de 4.8% de 1920 a 1930.

El Programa Bracero, 1942-1965

Todos los autores que estudiaron comunidades del occidente, encontraron que es precisamente en esta época cuando la migración se convierte en una práctica generalizada. Las facilidades dadas por los dos gobiernos posibilitaron que participaran miembros de los distintos grupos sociales. En algunas investigaciones se señala que eran principalmente los ejidatarios recién dotados, los que se integraban en mayor proporción, puesto que lo reducido de la estancia (entre 45 días y 6 meses) permitía que trabajaran por temporadas en Estados Unidos y regresaran para realizar los trabajos necesarios en su parcela. También se hace referencia a que esta estrategia era favorecida por la incapacidad de satisfacer sus necesidades únicamente con la parcela, debido tanto a su reducida dimensión, como a la falta de apoyo técnico y crediticio (Trigueros, 1994).

Lo mismo sucedió en Zamora, donde la corriente migratoria aumentó impulsada por la carencia de dinero para hacer producir la tierra entre los campesinos. Sin embargo, en este caso, el flujo se redujo a partir de la segunda mitad de los 1950s debido al auge económico en la zona, cuyo eje fue la agricultura beneficiada con riego y la introducción de cultivos más rentables. Este boom generó empleos, no sólo en el sector primario, sino también en el comercio y los servicios (Verduzco, 1992).

La migración indocumentada (1965-1986)

También hay coincidencia en las investigaciones analizadas, en el hecho que, a pesar de la terminación del Programa Bracero, la práctica migratoria continuó, aunque surgieron distintas modalidades en los desplazamientos. En algunas comunidades varios habían legalizado su situación laboral en Estados Unidos, por

lo que podían viajar cuando y a donde quisieran; así como ir legalizando el status de los demás miembros de sus familias. Pero en la mayoría de los casos se vieron obligados a migrar como indocumentados, lo que se facilitaba por la experiencia adquirida en la práctica y por la existencia de redes más o menos establecidas en distintas regiones de la Unión Americana, principalmente, en California.

Como ejemplos de las formas que adoptó la migración en este período, podemos mencionar el caso de Gómez Farías, donde prevalecieron los desplazamientos temporales, por objetivos. En los primeros meses del año partían a California, para regresar en los meses finales. A principios de los 1980s comenzaba a extenderse la tendencia a "invernar" en Estados Unidos, ya que los costos económicos de los viajes eran muy altos (López Castro;1986:76-77). Antes de 1982 muchos "gomeños" llevaban a sus familias con ellos, pero, debido al enorme aumento de los precios del transporte, la vigilancia del SIN y los mayores riesgos que implicaba el paso como indocumentado, esa tendencia se redujo. Sólo quienes tenían visa continuaban llevando a la familia (López Castro; 1986: 85-87).

En Los Altos de Jalisco, también fue creciendo la práctica migratoria, sobre todo en los municipios del centro de la región. En algunas zonas, el desarrollo económico, debido en gran medida al auge lechero, fue capaz de retener a muchos migrantes potenciales gracias a la oferta de atractivos empleos y a la posibilidad de éxito de pequeños negocios en el área de los servicios, financiados, muchas veces, con los dólares obtenidos de la migración (Alarcón y de la Peña, 1989).

A diferencia de lo que ocurría en las zonas rurales, en Zamora se mantuvo la tendencia a la baja, en términos relativos, de la práctica migratoria; aunque sí creció en números absolutos, lo que no es de extrañar dado el gran aumento de la población. Sin embargo, la mayoría de los zamoranos no dependía económicamente de la migración, y más bien recurrían a ella con un fin específico. Por este motivo, Verduzco (1992) sólo encontró que 19% de los migrantes entrevistados eran los que habían ido cuatro veces o más.

Areas de origen en México

Tradicionales

Tres entidades han sido clasificadas consistentemente en los primeros lugares como proveedoras de migrantes: Jalisco, Michoacán y Guanajuato. A ellas se agregaron Chihuahua, Durango y Zacatecas.

Gamio señalaba en 1930 que el 54.3% de los migrantes mexicanos provenía de esos tres estados del centro-occidente de México (Michoacán, Guanajuato y Jalisco), siguiéndolos en importancia Nuevo León, Durango y el D.F. (Gamio, 1930) (ver Cuadro 1).

Cuadro 1
Estados de origen de los migrantes por orden de importancia, según diversos autores

	Gamio (1926-28)	Samora (1968-70)	ENEFNEU* (1978-79)	ETIDEU** (1984)
Michoacán	20.0	8.3	8.4	13.1
Guanajuato	19.6	8.3	17.9	8.9
Jalisco	14.7	7.5	13.9	11.8
Nuevo León	8.0	6.1	1.5	
Durango	5.9	9.9	5.0	5.9
DF	5.0	1.0	1.7	3.1
Chihuahua	4.4	18.5	12.6	11.9
Zacatecas	6.9	11.8	5.7	
S. Luis Potosí	7.3	4.4	2.6	
Baja Calif.	0.5	1.6	5.0	3.6
Total	78.1	75.4	80.7	68.1

* Sólo se utilizó la información de la población que en el momento de la encuesta se encontraba en Estados Unidos.

** Lugar de nacimiento

Fuentes: Gamio (1930); Samora, 1971: 92; Zazueta y Corona, 1979: 129, y CONAPO, 1986

Areas nuevas

En 1969, el equipo de Julián Samora encontró que el porcentaje que ocupaban los primeros tres estados era de sólo 24.1%, pero que, con Chihuahua y Durango —que superaban a los tres primeros— ascendía a 52.5% (Zamora, 1970).

En la ENEFNEU (1978-79) Michoacán pierde peso, quedando en quinto lugar, después de Guanajuato, Jalisco, Chihuahua y Zacatecas; alcanzando el conjunto, 64.9%. En la ETIDEU (1984), Michoacán vuelve a encabezar el grupo y los cinco estados mencionados reducen su peso a únicamente 39.7%; lo que nos hace pensar que la práctica migratoria se va extendiendo en el país. Estados que antes no destacaban presentan porcentajes más o menos altos, por ejemplo, Zacatecas, Baja California, Guerrero y Oaxaca.

Por otro lado, en la investigación del grupo de Zamora, 84% de los encuestados provenía de áreas rurales, en la ENEFNEU[4] el porcentaje se había reducido a 69.8%; no obstante lo cual, resultaba ser mayor que el observado para el conjunto de la población mexicana en 1978 y que era de 53%.

Si en lugar de considerar el lugar de nacimiento en la ETIDEU, tomamos el de residencia, aumenta el peso de los estados fronterizos, especialmente de Chihuahua, al que corresponde el 15.7%; Baja California, el 10.2%; y Sonora, el 5.2%. Mientras pierden importancia los estados del centro de la república, lo que muestra cómo muchos de los migrantes cambian su residencia a la zona fronteriza, antes de migrar a Estados Unidos.

Areas de recepción en Estados Unidos

Areas tradicionales

1900-1942

De acuerdo a la información del Censo Norteamericano presentada por Gamio (1930); a principios de siglo Texas superaba con mucho a los demás estados de la unión en cuanto a la atracción de migrantes, ya que ahí se encontraba más de la mitad (68.7%) de la población de origen mexicano. Lo seguía Arizona con 13.7%, mientras California incluía únicamente 7.8% y Nuevo México, 6.4%. Sin embargo, la situación fue cambiando, en el censo de 1920, el peso de la población mexicana en Texas se había reducido un poco (52.5%), mientras el de California se había más que duplicado (18.8%), superando con ello a Arizona (12.8%). Nuevo México también bajó su participación (4.2%), y Colorado adquirió cierta presencia (2.3%). El orden se modifica cuando se consideran las *money orders* de 1926-1927, ya que entonces California presenta el primer lugar (36.2%), mientras de Texas sólo proviene el 15.7%; de Arizona 4.8% y de Nuevo México, 1.4%. En cambio, el estado de Illinois que en los censos presentaba un porcentaje muy bajo, alcanza una proporción de 12.2%; Indiana, de 5.1%; Michigan, de 3.4% y Pennsylvania de 1.8%. Es probable que, además de la creciente demanda de trabajadores mexicanos en los estados norteños del este y medioeste, influyan los salarios más altos en esas regiones alejadas, así como el hecho de que en los estados fronterizos, muchos de los mexicanos censados ya no mantuvieran relación económica con familiares en México.

Por otro lado, los migrantes que se ocupaban en la agricultura se desplazaban continuamente durante el verano y el otoño siguiendo el calendario de las cosechas a través de varios estados de la unión americana. Muchos de ellos regresaban, en invierno a México (Gamio, 1930: 43).

Las estrategias también cambian en cada región. Por ejemplo, los alteños de Jalisco se organizaban en pequeños grupos y se dirigían a El Paso, Texas, y desde ahí se internaban a los estados del centro y este, en donde se empleaban como trabajadores no calificados en la construcción y mantenimiento de la vía del ferrocarril y en fundiciones (Alarcón y de la Peña, 1989).

Cuadro 2
Distribucion de los migrantes mexicanos en los estados de la union americana, en 1900, 1920, 1926–1927, 1978–1979 y 1984

Estado de Residencia	GAMIO 1900	GAMIO 1920	ENEFNEU (1926-1927)	ENEFNEU (1978-1979)	ETIDEU (1984)
California	7.8	18.8	36.2	47.3	54.1
Texas	68.7	52.5	15.7	27.4	34.2
Illinois	0.2	0.8	12.2	7.4	0.2
Indiana	0.0	0.1	5.1		
Arizona	13.7	12.8	4.8	2.0	7.3
Michigan	0.1	0.3	3.4		
Pennsylvania	0.1	0.0	3.1		
New Mexico	6.4	4.2	1.4	2.7	1.0
Colorado	0.3	2.3	2.3	1.8	0.2

Gamio se basó para 1900 y 1920 en el Censo Norteamericano; para 1926-1927, en la proveniencia de *money orders* depositadas en Estados Unidos y destinadas a México, en los periodos de julio- agosto, 1926 y enero-febrero, 1927.

La información de la ENEFNEU y de la ETIDEU se refiere a migrantes, en la primera se incluyen documentados e indocumentados, mientras que en la segunda únicamente indocumentados.

Fuentes: Gamio, 1930; CENIET, 1982, y CONAPO, 1986

En general, y como se observa en las distintas investigaciones, había una gran dispersión de los migrantes en esta primera etapa. En el caso de Jaripo, iban a Chicago, Indiana y Michigan, principalmente; aunque hubo quienes fueran a Colorado, Wyoming, Nebraska, Pennsylvania, Texas, Kansas y California. La mayoría de ellos regresaron cuando las crisis, algunos de la de 1921–1922 y otros, de la de 1929 (Fonseca: 1986).

Programa Bracero

Durante el Programa Bracero, el abanico de estados también fue amplio, Texas, California, Arizona, Indiana, Delaware, Michigan, Arkansas, Montana y Washington, entre otros. Sin embargo, comenzaba a concentrarse la migración en los estados del suroeste, principalmente, en California (Fonseca, 1986; Trigueros, 1994; Alarcón y de la Peña, 1989).

Areas nuevas

En la ENEFNEU se encontró que los estados con porcentajes más altos de migrantes mexicanos eran, por orden de importancia, California con 47.3%; Texas con 27.4%; Illinois con 7.4%; Nuevo México con 2.7% y Arizona con 2%.

Como se ve en el cuadro anterior, en la ETIDEU adquieren mucho mayor peso los estados fronterizos de California, Texas y Arizona; en tanto que se reduce la importancia de los más lejanos, como Illinois y Colorado. Es muy probable que influya el hecho de que el INS, opera mucho más activamente en la zona fronteriza; de manera que, para los que logran alejarse más, aumentan las probabilidades de permanecer en Estados Unidos y regresar cuando lo decidan y no expulsados, motivo por el que no fueron captados por esta encuesta.

Como sucedía en los períodos anteriores, la práctica migratoria difiere en cuanto a los lugares de destino en las distintas regiones. Aunque en todas las investigaciones revisadas se destaca el predominio de California, varía el peso de otros estados como Texas, Illinois y Arizona. También dentro de California se han señalado zonas diversas. Alarcón (1986:345) menciona que los chavindeños (Mich.) se dirigían a cuatro regiones de California y que eran, por orden de importancia: el Valle de San Joaquín, el Valle de Salinas, la bahía de San Francisco y un barrio del centro de Los Angeles. Para los jaripeños los polos de mayor atracción eran Los Angeles, Oxnard, San José y, sobre todo, el condado de San Joaquín (Fonseca y Moreno;1988). López Castro (1986) encontró en Gómez Farías que la mayoría se dirigía a Watsonville o a lugares cercanos a San Francisco.

Perfil demográfico de los migrantes

Edad

Gamio (1969), basándose en la información de sus 61 entrevistas señalaba que la edad de los migrantes fluctuaba entre los 20 y los 60 años, con alta proporción de gente de edad madura, las mujeres eran, en los pocos casos que analizó, de edad avanzada.

De acuerdo al equipo de Samora, 70.8% tenían en el momento de la entrevista 30 años o menos. Si consideramos su primera participación, 85.8% lo hizo en esas edades (Samora, 1971: 90).

En 1978-79, según la ENEFNEU, el porcentaje de menores de 30 años se había reducido a 54.7%. Pero en 1984, de acuerdo a la ETIDEU, era de 74.2%, siendo el promedio de edad de 26.2. Es probable que la diferencia se deba a que la ENEFNEU incluía migrantes con documentos, y según varios de los trabajos en microrregiones, los mayores únicamente migraban cuando disponían de los mismos.

Si consideramos la diferencia de edades por sexos, en esta última encuesta, se encontró que entre los hombres el porcentaje de menores de 30 años era de 75.3% y el de las mujeres, de 65.4%; lo que nos muestra que las mujeres tienden a migrar mayores.

Sexo

La gran predominancia masculina en esta práctica ha sido destacada en todas las investigaciones. En las entrevistas hechas por Gamio (1969), en la década de los 1920s, incluyó a muy pocas mujeres. Todas viajaron para acompañar al marido o a la familia.

En la ENEFNEU (1978-79) se encontró que 83.9% de los migrantes a Estados Unidos eran hombres; en la ETIDEU (1984), el 89.1%. Es probable que, otra vez, la diferencia se deba a que es más alto el porcentaje de mujeres que migran con documentos.

Aun cuando en todas las investigaciones se ha resaltado la poca participación de las mujeres (Diez Canedo, 1983; Alarcón, 1986, etc.), muchos autores notaron un mayor involucramiento en los 80s, por la abundancia de oportunidades de empleos en los que se prefiere mano de obra femenina. Sin embargo, varía la situación, al igual que sucede con la migración familiar. Ambos aspectos están muy relacionados con el acceso a los documentos para legalizar su situación, la existencia de redes en Estados Unidos y las pautas culturales de cada comunidad.

Alarcón (1986:345) encontró que a los hombres de Chavinda (Michoacán) no les gustaba casarse en Estados Unidos ni llevar a sus familias con ellos pues consideraban que no había condiciones para un desarrollo sano. En cambio, en Jaripo se había extendido la migración familiar, lo que es entendible dada la cantidad de vecinos de la localidad que contaban con documentos. Esto resultaba de suma importancia para poder incorporar, poco a poco a los otros integrantes, quienes iban legalizando su situación, hasta que finalmente se podía desplazar todo el grupo completo (Fonseca, 1986). Esta estrategia muestra la importancia que ha tenido la legalización de los migrantes en el incremento de la migración femenina y familiar. En Gómez Farías se abandonó esta práctica en los primeros años de la década de los 1980s debido a la carestía del viaje y a los peligros que implicaba, ya que en este caso la mayoría no contaba con documentos. Sin embargo, 20.2% de los migrantes eran mujeres, la mayoría de las cuales iban desde 1976, explícitamente a trabajar. Además, únicamente el 27.11% de ellas viajaba acompañando a los hombres de la familia y para realizar los trabajos domésticos (López Castro, 1986). En cambio, Verduzco (1992) señala que en Zamora, la migración era casi totalmente masculina.

Estado civil

Gamio (1930, 44) señalaba que, como regla general, los trabajadores agrícolas eran hombres, solteros, o bien, casados que dejaban sus familias en México o en las ciudades americanas. Pero que los empleadores preferían hombres con familia por dos razones: permanecían en el trabajo y sus familias ayudaban al jefe del grupo, con lo que el empleador disponía de más mano de obra.

En la investigación de Samora se observó que 48% eran solteros (Bustamante, 1976: 31).

En general, se ha encontrado que migran en proporciones semejantes los casados y los solteros, aun cuando puede cambiar la duración de la estancia, de acuerdo al estado civil, y la utilización de los ingresos devengados.

Escolaridad

Entre los entrevistados por Gamio (1969), la escolaridad era sumamente baja, de menos de 5 años, con una fuerte proporción de analfabetas, lo que no es de extrañar dadas las condiciones de la mayor parte de la población mexicana en las primeras décadas de este siglo.

El equipo de Zamora establecía que 28% nunca había asistido a la escuela y 90% no había terminado la primaria (Zamora, 1971: 90). La proporción había bajado a la mitad en 1984, aunque todavía era muy elevado el porcentaje de analfabetas detectado por la ETIDEU, 14% (17.6%, de las mujeres).

De acuerdo a la ENEFNEU, el promedio general de años cursados y aprobados por los migrantes era de 4.9, nivel que se mantuvo en la ETIDEU (en el caso de las mujeres, 4.6) (CONAPO, 1986). En la ENEFNEU 34.3% había estudiado menos de 4 años y sólo el 24.6% completaron 7 años o más. Esta proporción era muy inferior al nivel que existía en Estados Unidos, donde de las personas mayores de 17 años, únicamente el 3.4% tenía entre 0 y 4 años de instrucción; el 14.1% tenía cursados entre 5 y 8 años y el 82.5% más de 8 años (CENIET, 1982).

En algunos estudios de caso se encontró que el grado de escolaridad alcanzado se relacionaba positivamente con una mayor probabilidad de emigrar, lo que daba lugar a que se fuera la población más joven, más productiva y mejor educada. Sin embargo, no se trata de una situación generalizada.

En la ciudad de Zamora participaban en la migración los trabajadores con bajo nivel educativo (de 0 a 3 años de escolaridad), siendo todavía menor el nivel entre los migrantes recurrentes. Verduzco señala que es probable que este grupo enfrentara serias limitaciones para insertarse de forma ventajosa en el mercado laboral que abrió el dinamismo económico y comercial zamorano, lo que los obligaba a integrarse en la migración laboral como una estrategia para valorizar

mejor su fuerza de trabajo. En este orden de ideas propone que, a diferencia de la migración de origen rural, que recluta fundamentalmente a los sectores medios del campesinado, la migración urbana se nutre de los contingentes de trabajadores menos favorecidos (Verduzco, 1992).

Nivel social

Se ha señalado que, en general, migran más aquellos cuya actividad, agrícola o de otro tipo, les permite situarse por encima del nivel de subsistencia, pero no los que cuentan con granjas capitalistas eficientes, ya que sus ingresos en la localidad donde viven son suficientes para vivir bien (Diez Canedo, 1984). Al respecto, López Castro (1986: 88-96) sugiere que para poder migrar se requiere de una fuerte inversión (entre 300 y 350 dólares). Sin embargo, hace referencia a que hay otro elemento que favorece la migración, independientemente de la posición económica: las redes sociales. Por otro lado, plantea que los ricos viajan poco porque tienen posibilidad de rentar o comprar parcelas e invertir en la agricultura comercial. Un aspecto importante que menciona es que, en igualdad de condiciones la gente prefiere no moverse geográficamente.

Perfil ocupacional de los migrantes

Sectores económicos de ocupación en México

Tradicionales

Aunque la mayoría de los entrevistados por Gamio (1969) en los 1920s se dedicaba a labores agropecuarias, como peón, mediero o minifundista, era significativa la presencia de pequeños comerciantes, obreros, empleados y artesanos. El autor lo atribuía a su elevada movilidad geográfica y ocupacional desde antes de su viaje al norte, ya que muchos residían en una gran ciudad antes de migrar.

Durante el Programa Bracero en la mayoría de las comunidades michoacanas migraban tanto ejidatarios, como arrendatarios ecuareros y jornaleros (Fonseca, 1988; López Castro, 1986; Trigueros, 1994).

Nuevos

En 1971, de los entrevistados por el equipo de Zamora, 57% habían estado trabajando en México en el sector agrícola y únicamente 12% laboraron en trabajos calificados (Samora, 1971: 91).

En la encuesta del CENIET (1982), se señala que el 58.5% de la población migrante se ocupaba en el sector primario, 15.1% en el secundario y 23.5% en el terciario.[5] Estas proporciones son diferentes a las que presentaba entonces la

población mexicana en su conjunto, ya que únicamente el 39.3% se ocupaba en el sector primario; 21.4% en el secundario y 38.7% en el terciario.

En la ETIDEU, el 39.4% laboraba en el sector primario, 33.1% en el secundario y 26.5% en el terciario.

En cuanto a la ocupación desempeñada, el 59.6% de la muestra de la ENEFNEU desempeñaba labores agropecuarias; el 17.3% eran trabajadores no agrícolas y el 9.4% trabajadores en servicios y transportes (CENIET, 1982).

En la ETIDEU, el 39.8% desempeñaba labores agropecuarias; 39.3% eran trabajadores no agrícolas, 8.5%, trabajadores en servicios y transportes y 7.6% se ocupaban en el comercio. Al analizar la información por sexos, sobresale el hecho de que sólo 5.6% de las mujeres trabajaba en el sector primario; 30.6% en el secundario y 60.2% en el terciario, de las cuales el 21.4% correspondía a actividades en unidades domésticas no productivas (CONAPO, 1986).

De acuerdo a las investigaciones revisadas, la migración a Estados Unidos se presenta tanto en comunidades con agricultura tradicional, afectada por las malas condiciones de la tierra y lo reducido de las parcelas; como en las que se han implementado técnicas modernas con la consiguiente orientación de la producción al mercado (Trigueros; 1994).

Otro aspecto interesante de mencionar es que, entre los migrantes que se encontraban en Estados Unidos había 27.2% (110,719) que no estaban trabajando antes de su viaje. De ellos, el 15.2% estaba desempleado, 14.1% era trabajador no remunerado y 40.3% se ocupaba en quehaceres domésticos (Ibid.).

Llama la atención el hecho, señalado por Alarcón, de que fueran los que se ocupaban en actividades agrícolas los que optaban por la migración internacional, lo que se podría atribuir a que los que tenían cierta calificación, podían acomodarse en el mercado laboral mexicano —y que coincide con la observación de Verduzco sobre el nivel educativo de los migrantes—. Por ese motivo, los que tenían mayor preparación preferían migrar al interior del país, la mayoría de los cuales lo hacía en forma definitiva.

Un aspecto en el que existen diferencias de una investigación a otra es el que se refiere al peso que tenían los poseedores de tierra en el conjunto de migrantes. Algunos autores encontraron que eran ellos los que preferentemente participaban en esta actividad; otros, que eran aquellos que no tenían los que más viajaban y más a menudo.

López Castro (1986: 92-96), por su parte, encontró que 60% de las familias de ejidatarios enviaban migrantes continuamente y que 37.7% de los jefes ejidatarios migraban.[6] Sin embargo, los que tenían más viajes en promedio eran los que disponían de parcelas medianas (entre 4 y 6 hectáreas); siguiéndolos los de 7 a 10 hectáreas y, al último, los de 1 a 3 hectáreas. Plantea que existe un límite arriba del cual dejan de viajar, y lo fija, para el caso de Gómez Farías, en 10 hectáreas de

riego. También señala que migraban más los poseedores de tierras de riego y sus hijos, en relación a los que disponían de tierras de temporal. El autor supone que esto se debía a que en estas últimas se necesitaba la mano de obra familiar para el trabajo en la parcela, o bien, a la falta de recursos para financiar el viaje. Sin embargo, en Chavinda, un poco más de la mitad del flujo migratorio (57.2%) estaba formado por jornaleros.

Alarcón encontró que migraban más los jornaleros, y de los poseedores, los que tenían tierras de riego.

Según Fonseca (1988), aunque en Jaripo, la actividad principal era la agricultura, a partir de los 1970s se notaba un creciente abandono de la agricultura de subsistencia, debido a que un número importante de familias vivía exclusivamente de la migración a Estados Unidos.

Sectores económicos de ocupación en Estados Unidos

Tradicionales

Santibáñez (1930) señala que a fines del siglo pasado, los mexicanos que llegaban a las poblaciones fronterizas del estado de Texas se empleaban en la agricultura y las industrias de la construcción, ferrocarrilera y automotriz.

En 1920, los mexicanos continuaban trabajando en la agricultura, la ganadería, la industria ferrocarrilera, y la de la construcción, urbana y caminera, pero además lo hacían en la petrolera, la extractiva y la ladrillera. También laboraban como empleados de restaurantes y estibadores. Menciona que existían algunos casos de trabajadores calificados como artesanos, sastres, impresores, peluqueros, comerciantes y médicos. Por último, los trabajos en la industria y los calificados se realizaban en el norte, ya que, según el autor, en el sur, ese tipo de trabajos estaban cerrados para los mexicanos (Ibid., 88-89).

La información de Gamio (1930) coincide, en términos generales con la de Santibáñez, y se refiere a que en la primera década del siglo, los trabajadores mexicanos se empleaban principalmente en el cultivo y la cosecha de algodón, maíz, caña de azúcar y frutas; pero también en los ferrocarriles, en los ranchos ganaderos y en la minería. Para la década siguiente (1910-1920) la demanda de fuerza de trabajo mexicana se había intensificado y se ocupaban en el cultivo de la remolacha y en industrias tales como la acerera, la cementera, la automotriz y las empacadoras de alimentos del este y el medioeste (Gamio, 1930: 25-27). Señala que la demanda de trabajadores mexicanos en la industria era pequeña, pero constante, y, generalmente, el trabajador mantenía su posición durante todo el año. El motivo por el que ellos se desplazaban al sur era por lo riguroso del invierno; siendo probable que al año siguiente regresaran a su mismo trabajo. En cambio, la

demanda para las labores agrícolas era muy grande, pero variable, y se limitaba a ciertas estaciones del año y a ciertas labores. De tal manera que para diciembre la demanda se acababa enteramente, y muchos trabajadores se veían obligados a regresar (Ibid., 43).

Plantea que la distribución geográfica de los migrantes parecía comprobabar que una alta proporción de ellos estaba empleada en el trabajo rural, en pequeños pueblos y ciudades, mientras un grupo reducido laboraba en empresas industriales en ciudades como Chicago, Los Angeles, San Antonio y los alrededores de Pittsburgh (Ibid., 29).

Sin embargo, entre sus entrevistados la agricultura no era la actividad principal. La mayoría de sus informantes se ocupaban en trabajos poco calificados, como peones del ferrocarril, jornaleros agrícolas, en la construcción de vías de comunicación y de casas. También obtuvo información de obreros de las industrias minera, cementera, fundidora y empacadora. Algunos laboraban como trabajadores en servicios y otros pocos eran artesanos o comerciantes en pequeño. Encontró que tenían una extrema movilidad ocupacional, lo que, desde su punto de vista, reflejaba la precariedad de los empleos y la sobreexplotación y discriminación que sufrían (Gamio, 1969).

Fabila (1932) también resalta la importancia de empleos como la construcción de carreteras, la minería, la industria manufacturera y la ferrocarrilera y añade la pizca del limón —que consideraba era uno de los menos pesados y, quizá el mejor retribuido— y la pizca del algodón.

Las investigaciones en comunidades coinciden con las observaciones de los autores mencionados en el sentido de que en esta primera etapa la migración se dirigía a sectores económicos no agrícolas.

En cambio, durante el Programa Bracero, la mayoría laboró en la agricultura; aunque hubo casos aislados que se ocupaban en la industria ferrocarrilera, la maderera, el cuidado de bosques y hasta como cocineros (Fonseca, 1986).

Modernos

De acuerdo a la investigación del equipo de Samora (1971), de los entrevistados que lograron trabajar (43%) la mayoría estaba empleada en la agricultura. Aun cuando sabían que la mejor manera de evitar ser aprehendidos era alejándose de la frontera, los primerizos, sin contactos en Estados Unidos buscaban empleo en la agricultura de los estados fronterizos debido a que, siendo que la mayoría provenían de áreas rurales, eso era lo que sabían hacer. De acuerdo a sus observaciones, era en esa zona donde obtenían un cierto grado de socialización, y aprendían acerca del código no escrito del comportamiento del "mojado" (Samora, 1971: 74-75).

La información de la ENEFNEU nos permite tener un acercamiento a los sectores de actividad de los migrantes de toda la república, aunque únicamente se trata de aquellos que estaban en su vivienda y podían informar sobre su experiencia en el último viaje. De ellos, el 37.1% laboraba en el sector primario; 24.8% en el secundario y 37.6% en el terciario (CENIET, 1982, 144).

Según la ETIDEU, los porcentajes eran de 45% en el sector primario; de 21.5% en el secundario y de 33.1% en el terciario. En cuanto a la ocupación, el 45.9% eran trabajadores agropecuarios; 33.9% laboraban en el proceso industrial; 17.4% en servicios y transportes y 1.8% en el comercio. Por otro lado, existen comportamientos diferentes entre las mujeres migrantes. Unicamente el 12.7% de ellas se desempeñaban en el sector primario; 7.8% en el secundario y 78.7% en el terciario; de las cuales, 61.6% laboraba en unidades domésticas no productivas (CONAPO, 1986).

A pesar de que la agricultura seguía siendo la actividad en la que se ocupaba la mayor proporción de migrantes, el peso de esta actividad variaba entre los migrantes de cada comunidad, aspecto que está muy relacionado con el estado norteamericano al que se dirigían.

En la investigación de Alarcón en Chavinda (1988), el 66.9% se ocupaba en actividades agrícolas, 15.8% en actividades manuales y 12.6% en servicios no calificados. En cambio, un elevado porcentaje de jaripeños se incorporaba en grupos familiares al trabajo agrícola en California (a pesar de contar con papeles para entrar legalmente) (Fonseca, 1988). Lo mismo sucedía entre los migrantes de Los Altos de Jalisco, quienes se ocupaban en el sector primario tanto en California como en Texas. Los que se ocupaban en la industria se iban a Chicago o a Los Angeles.

De los migrantes provenientes de Chavinda, aunque el trabajo agrícola era el más favorecido, cada vez encontraban más posibilidades de ocuparse en actividades no agrícolas, lo que además se debía a que en el campo cada vez había menos oportunidades de empleo por la mecanización de los cultivos. Esto daba lugar a que las estancias fueran más largas (López Castro, 1986).

Niveles de ingreso

En México

Gamio señalaba, basándose en fuentes oficiales mexicanas, que en 1926, el promedio de salario diario para los trabajadores agrícolas en México era de 0.91 pesos, y el de los trabajadores industriales, de 1.40; o sea, en promedio 1.15 pesos, lo que significaba 0.57 dólares. Pero que en las regiones de las cuales provenían la mayor parte de los migrantes, el salario diario era todavía más bajo. Decía que, de acuerdo a sus cálculos, el salario mínimo para que el trabajador con una familia de

cinco miembros, pudiera sobrevivir, aun sin educación y recreación, o sea sólo con su urgente necesidad de vivir, debía ser de 247.48 pesos al mes (123.74 dólares). En estados como Aguascalientes y Tamaulipas, debía ser más alto, puesto que el costo de la vida era mayor. Sin embargo, con el salario promedio de 1.15 pesos al mes únicamente sería 35.65 pesos; lo que significaba que se debería incrementar aproximadamente ocho veces para que pudiera cubrir el costo de las necesidades de vida normales (Gamio, 1930: 35-37).

En Estados Unidos

Santibáñez (1930: 93), encontró que en Texas los jornaleros trabajaban de 10 a 12 horas diarias y recibían a cambio 1.25 o 2 dólares, según la época del año y la disponibilidad de migrantes. Pero en el norte, el salario era doble o triple ya que no había tanta competencia como en los estados fronterizos.

Gamio (1930: 38) señalaba que era muy difícil establecer los salarios de los migrantes mexicanos puesto que eran mucho más bajos que los registrados en las estadísticas oficiales y su nivel fluctuaba cuando cambiaba la demanda. Por estos motivos prefirió utilizar datos obtenidos de su trabajo de campo, de la información consular y de algunos empleadores de trabajadores mexicanos. De acuerdo a esta información el pago mínimo era de 1.50 dólares al día y, un poco más bajo en algunas partes de Texas; mientras que en otras regiones la remuneración llegaba hasta 6 dólares diarios. Al establecer un promedio con esta información obtenía un salario de 3.38 dólares diarios o 104.78 al mes de treinta y un días. Este pago era seis veces mayor que el de 17.67 dólares al mes que el trabajador ganaba en México.

Según sus cálculos, el salario en México constituía la octava parte del costo de la vida, en tanto que en Estados Unidos se mantenía en relación con el pago que recibían. En general, en México el costo de la vida era muy alto y el pago muy bajo, mientras que en Estados Unidos el pago era mucho más alto y el costo de la vida, menor (Ibid., 38-40).

En Estados Unidos el trabajador mexicano no sólo ganaba lo suficiente para satisfacer sus requerimientos elementales para un mínimo de bienestar; sino que también gastaba dinero para educación, recreación, etc. Los trabajadores mexicanos en Estados Unidos poseían propiedades que nunca lograrían con los ingresos en México: automóviles, fonógrafos y refrigeradores (Ibid., 41).

Fabila (1932: 55) señalaba que aunque el salario mínimo en Estados Unidos se había establecido en 5 dólares por ocho horas diarias de labor, y 3 para las mujeres; el mexicano se quedaba satisfecho con 15 o 16 dólares semanales.

En la encuesta de Samora (1971), de los que lograron trabajar antes de ser aprehendidos, 26% ganaban menos de un dólar por hora; 56%, entre 1.00 y 2.00

Dólares; 14%, entre 2.0 y 3.00, y 3% ganaba arriba de 3.0 dólares por hora. También realizaron un estudio en El Paso en 1969 y ahí encontraron que los salarios para indocumentados en la agricultura eran de entre 0.75 y 1.10 dólares. No se podían quejar porque los denunciaban y había suficiente repuesto. Las mujeres que trabajaban en unidades domésticas no productivas conmutaban diario de México y ganaban 2.00 dólares diarios (Samora, 1971: 98-99).

De acuerdo a las observaciones del Senador Ralph Yarborough (1968:188-190), citado por Samora (1971: 24) Texas era uno de los estados con más bajas remuneraciones; era uno de los 13 que no tenían salario mínimo. Pero que los otros 12 eran predominantemente rurales, en tanto que Texas era un rico estado industrial, y su agricultura se encontraba entre los tres principales productores.

Entre los encuestados en la ETIDEU en 1984, el ingreso diario más usual era en 1984 de 21 a 30 dólares, ya que el 39.7% ganaba dentro de ese rango; sin embargo había 27.9% que ganaban menos y un 8.6% que ganaba 41 dólares o más.

Entre los migrantes de La Purísima entrevistados en 1981, el ingreso semanal más usual era de 100 a 199 dólares (72% de los entrevistados), y aunque variaba según la rama de actividad, en todas era predominante.[7]

En Gómez Farías el sueldo mensual promedio en 1982, de acuerdo a López Castro (1986) era de 624 dólares, del cual gastan aproximadamente el 32.1% en casa y comida; 16% en otros gastos, envían a sus casas 32.1% y todavía ahorran 19.9%.

Migración interna

Es común encontrar en los poblados donde se practica la migración internacional, que ésta se combina con la migración interna, aunque los destinos y el peso de cada modalidad varía de una comunidad a otra. Sin embargo, a pesar de las diferencias, todos los autores coinciden en que la que se dirige a Estados Unidos es mucho más importante. Esta última es casi siempre es temporal, mientras que la que se dirige al interior de la República Mexicana es en muchos casos permanente. Llama la atención que los dos tipos de desplazamientos se pueden encontrar en una misma familia y aún en un mismo individuo; en estos casos se trata de migraciones temporales.

En Chavinda, el 25.4% de los entrevistados por Alarcón habían estado trabajando en Estados Unidos pero sólo 6.4% lo había hecho en algún otro lugar de México. Por otro lado, como ya vimos, mientras los trabajadores agrícolas optan en gran proporción por Estados Unidos, entre los trabajadores manuales y no manuales la incidencia en la migración interna es un poco más alta, aunque, también inferior a la que se dirige a Estados Unidos. En La Purísima, la migración al Distrito Federal era usual, pero también muy inferior a la que se dirigía al vecino país.

Características socio-demográficas de los flujos de migrantes laborales mexicanos hacia Estados Unidos, por regiones de procedencia (ENADID and EMIF Surveys)

Características generales

Los datos muestran que las zonas de expulsión tradicionales mantienen los primeros lugares, aunque su peso en el conjunto se ha reducido. En 1930 Gamio señalaba que el 54.3% de los migrantes mexicanos provenía de tres estados del centro-occidente de México (Michoacán, Guanajuato y Jalisco). En la ENADID (1992), esos tres estados aportaban el 35.2%, y en la EMIF (1993-1994), el 30.4% de los que se dirigen a Estados Unidos y 36.5% de los que vienen de regreso. También, según las investigaciones revisadas, a lo largo del tiempo se incorporaron otros estados como Zacatecas, Durango y Chihuahua, a los que se han agregado algunas entidades fronterizas, del centro de México, y los de la zona Pacífico Sur. De acuerdo a la ENADID, después de los tres estados tradicionales se ubicaron: México, en cuarto lugar, Zacatecas, Durango, Guerrero, Chihuahua, el Distrito Federal, Nuevo León y Tamaulipas, en ese orden de importancia.[8]

De acuerdo a la ENADID, las personas que migraron entre 1987 y 1992 constituyen el 2.34% de la población, 1.09% habían retornado y 1.24% permanecían en Estados Unidos. Si consideramos la participación por entidades, destacan Michoacán, donde representan el 7.78%; Zacatecas (7.74%), Durango (6.42%) y Colima (5.68%); mientras para los estados del sureste sólo constituyen el 0.1% en Tabasco, 0.2% en Chiapas y 0.3% en Tabasco y Campeche. De los michoacanos habían regresado 4.39% y 3.98% de los zacatecanos, seguidos por los colimeños (3.35%) y los nayaritas (3.11%). Sin embargo, con la información disponible es difícil interpretar qué elementos podrían influir en estas diferencias.

Si consideramos a la población de 12 años o más, el 3.9% de ella ha ido a buscar trabajo en Estados Unidos, pero, en el caso de los hombres, el porcentaje es de 6.7%. Sobresalen los hombres mayores de 50 años, entre quienes el 11.4% ha estado en esa situación.

Tomando en cuenta la regionalización propuesta, y como ya habíamos señalado, el 36.5% de los migrantes registrados por la ENADID nació en la región I (mayor salida de la emigración). En el flujo de los migrantes que regresan de Estados Unidos (EMIF) el porcentaje es algo mayor, 37.4%; pero mucho menor en los deportados, 27.7%. La siguen, con un margen de diferencia muy grande, los de la región de las seis entidades (III) y la de la frontera norte (II) con el 18.4% y 18%, respectivamente. En la EMIF, en el flujo de los que vienen de Estados Unidos los porcentajes son: superior, el de la III, 24.5%, pero inferior el de la zona fronteriza, 18.1% (en los deportados, los de la frontera presentan un

porcentaje superior, 22%, frente a 20.4% de la III). Las regiones IV y V se encuentran a una distancia bastante amplia de las anteriores, ya que proporcionan el 13.1% y el 11.8%, de acuerdo a los datos de la ENADID y 11.2% y sólo 6.7%, respectivamente en el flujo de los que regresan de Estados Unidos. En el caso de los deportados existen diferencias importantes entre estas dos regiones, ya que la región V supera a la región IV con un amplio margen : 16.3% frente a 10.2%. Así, resulta más alto en el caso de la región V con relación a la ENADID y más bajo en la IV. Por último, la región VI (entidades del sureste) presenta una participación sumamente limitada en las dos encuestas, en la ENADID, 2.1%; en la EMIF, flujo norte-sur 2.0% y algo más alta, 3.5% entre los deportados.

Al considerar la región de residencia —que supone en algunos casos una migración previa— encontramos que en la ENADID**,** los cambios resultan insignificantes. Sin embargo, en la EMIF, en el flujo de los que vienen de Estados Unidos, pierden peso las regiones tradicionales I y III, así como la de Oaxaca-Guerrero, mientras ganan la del valle de México y la de la frontera, lo que no es de extrañar, dado que esas zonas constituyen polo de atracción, especialmente, algunos estados de la región II. En el flujo de los deportados, sólo la región fronteriza incrementa su porcentaje, que alcanza 32.1%. La región I que es la que le sigue, sólo constituye el 24.5%, la región III el 16.7% y la región IV y la región V, 9.7% y 14.3%, respectivamente. Esto nos lleva a constatar que, como se señala en investigaciones microrregionales, varios migrantes internacionales cambian su residencia, principalmente, hacia el norte, antes de ir a Estados Unidos.

Características sociodemográficas

Distribución por sexo

La población masculina sigue siendo preponderante, aún cuando el índice de masculinidad es muy diferente en cada una de las encuestas. En la ENADID el 26.2% de la población son mujeres, mientras que en la EMIF únicamente el 1.88% de los que provienen de Estados Unidos, y 5.6% de los migrantes que vienen del sur. La presencia femenina es mayor entre los deportados: 10.7%. Es probable que esto se deba a la mayor participación de jóvenes. La diferencia en cada una de las encuestas podría ser atribuible a que, según se ha detectado en los estudios microrregionales, muchas mujeres sólo migran cuando tienen papeles, y, cuando esto sucede, pueden viajar directamente desde su lugar de origen y regresar de la misma manera, sin necesidad de dirigirse a la frontera, por lo que no pueden ser captadas por la EMIF.

Si consideramos la distribución por regiones, volvemos a encontrar diferencias entre las encuestas. Así, por ejemplo, en el caso de los que vienen de Estados Unidos de la EMIF, la región V no cuenta con mujeres, y la región I y la región IV,

sólo con 1.2% y 1.5%, respectivamente. El porcentaje más alto es el de la zona fronteriza con únicamente 3.2%. Entre los deportados las diferencias por regiones son mínimas ya que el porcentaje de hombres fluctúa entre 82.3% en la región III y 86.2% en la región I.

En cambio, en la ENADID la región con más bajo porcentaje de mujeres es la del Valle de México, con 18.4%; y, al igual que en la EMIF, la que cuenta con mayor participación femenina es la de la frontera (32.5%).[9]

Distribución por edades

Se ha señalado, también, que en la migración laboral a Estados Unidos predominan los jóvenes, lo que se confirma en nuestras encuestas, aunque con diferencias entre ellas y en los distintos tipos de flujos. En la ENADID, el promedio de edad es de 25.8% ; muy semejante al de los deportados, 25.4. En el flujo de los que vienen de Estados Unidos el promedio es mucho mayor, 31.68, quizá debido a que algunos de ellos ya regresan de manera definitiva. De cualquier forma, si consideramos que se trata únicamente de población trabajadora, este promedio no resulta demasiado alto.

Tomando en cuenta el comportamiento por sexo, encontramos diferencias importantes en cada encuesta. En la ENADID, el promedio de edad de las mujeres es más bajo que el de los hombres (23.8% frente a 26.6% de los hombres) ; en la EMIF sucede lo contrario: el promedio es superior en las mujeres, aunque la diferencia es poco pronunciada. En el caso de los que regresan de Estados Unidos, 32.58 frente a 31.67 en los hombres**;** en el de los deportados, 27 frente a 25,7 en los hombres.

Si analizamos esta variable según el tipo de localidad de nacimiento vemos que en la EMIF las diferencias son muy pequeñas, tanto en el caso de los que vienen de Estados Unidos, como en el de los deportados, siendo mayor el promedio en los que nacieron en comunidades rurales (en los que vienen del norte, 32.8 en los de origen rural y 30.25 en los provenientes de ciudades; en los deportados, la relación es de 26.8 y 25.1, respectivamente). En la ENADID, la diferencia es todavía menor, 26 años en los de origen rural y 25.6 años en los que provienen de localidades urbanas.

También las diferencias por regiones de procedencia son pequeñas. En la ENADID los más jóvenes son los de las región Oaxaca-Guerrero (25.1 años), los mayores, los de las norteñas (26.9 años en la región II y 26.1 años en la región III). Esto podría deberse a la facilidad de los desplazamientos, sobre todo en el caso de las entidades fronterizas; y quizá podría influir la antigüedad de la tradición, ya que, como ya hemos visto, los estados sureños se integraron a esta práctica mucho más tardíamente. En los que vienen de Estados Unidos de la EMIF sucede algo

parecido, los promedios menores corresponden a las regiones más nuevas en la práctica migratoria, la región IV y la región V (28.5 años y 28.06 años respectivamente); siendo los mayores los de las regiones más tradicionales, la región I y la región III, con 33.4 años y 32.5 años, respectivamente. En los deportados la situación es contrastante, ya que el promedio más bajo es el de la región III, 24.6 años; y, el más alto, el de la región V, 27.7 años.

Según la ENADID, el 47.5% de los hombres migrantes está en los grupos de edad comprendidos entre los 15 y 24 años; ubicándose el 73.2% entre los 15 y los 34 años. La situación es semejante en el caso de las mujeres, aunque algo más concentradas en el grupo de 15 a 24 años, 49.1%, y menos entre los 15 y los 34 años (71.7%). Los deportados (EMIF) son mucho más jóvenes, el 72.9% se encuentra entre los 15 y los 29 años; alcanzando una proporción de 85.6% los que están comprendidos entre los 15 y los 34 años. En tanto que, de los que vienen de Estados Unidos, únicamente 31% está entre los 15 y los 24 años, y 65.7% entre los 15 y los 34 años. Como ya habíamos visto cuando analizamos los promedios, este tipo de flujo incluye un porcentaje más alto de migrantes mayores. Esta situación se hace más evidente en el caso de las mujeres, ya que entre los 15 y los 34 años sólo se encuentra el 52.5% de ellas.

Estado civil de los migrantes

En cuanto al estado civil de los migrantes, de acuerdo a la información de la ENADID, predominan los casados o unidos (unidos), aunque existen diferencias importantes entre sexos, ya que mientras en los hombres constituyen el 72.2%, en el caso de las mujeres, sólo el 58.3%. En cambio, en éstas es bastante elevado el peso de las separadas, viudas o divorciadas (desunidas), ya que es de 18.5% frente a únicamente 2.6% en los hombres. Quizá esto se deba a que un número importante de mujeres recurren a esta práctica cuando requieren recursos para sostener a su familia. En los solteros el porcentaje es semejante en ambos sexos (25.2% en los hombres y 23.2% en las mujeres). Esto parece demostrar que, a diferencia de lo que muchos suponen, la migración es más una estrategia para sostener al grupo doméstico, que una simple aventura.

En los que regresan de Estados Unidos de la EMIF, también los unidos superan a los solteros, aunque los márgenes son menores, 64.7% en los hombres y 57.3% en las mujeres. En este caso, la proporción de desunidos es muy reducida en los dos sexos, 1.5% en los hombres y 2.7% en las mujeres. También es más alto el porcentaje de mujeres solteras 40% (frente a 33% de los hombres). Llama la atención el caso de la región IV, pues en ella los solteros superan a los unidos (53% frente a 46.9%); en tanto que en las demás regiones se observan patrones semejantes al que presenta el conjunto de la población.

En cambio, entre los deportados, el 60.41% son solteros y 37.4% casados. Llama la atención que entre las mujeres, el porcentaje sea muy semejante 47.4% y 45.3%, respectivamente. La relación se invierte cuando se toma en cuenta el lugar de residencia de las mujeres deportadas (47.3% casadas y 44.8% solteras).

Distribución por tipo de localidad

Se ha señalado que aunque tradicionalmente los migrantes provenían de áreas rurales, esta tendencia se ha ido reduciendo, de tal manera que actualmente es mayor la proporción de aquellos que nacieron en localidades urbanas (de 15,000 habitantes o más). Sin embargo, de acuerdo a las dos encuestas, los migrantes de origen rural presentan porcentajes ligeramente superiores. En la ENADID, los de origen rural constituyen el 55.3% y entre los que proceden de Estados Unidos y viven en México, de la EMIF, 61.4%. Unicamente entre los deportados, los de origen urbano presentan un porcentaje mayor, 58.7%. Es posible que esta predominancia esté relacionada con la edad y la región de residencia, pues, como vimos, los migrantes deportados son más jóvenes y tienen mayor peso en los estados fronterizos, donde predomina la población urbana. También podría influir el hecho de que las redes que favorecen la migración son más fuertes en las comunidades rurales; por lo que serían los migrantes urbanos los que se encontrarían "desprotegidos" en el territorio americano. Sin embargo, únicamente se trata de hipótesis que podrían ser exploradas.

Por otro lado, si consideramos la localidad de residencia, la proporción de migrantes urbanos se incrementa ligeramente, debido a la migración previa de localidades rurales a urbanas que ya se ha señalado. En la ENADID aumenta a 44.7%, aún cuando continúa siendo mayor el peso de los que vienen de zonas rurales. En la EMIF, la población urbana que regresa de Estados Unidos (53.6%) sí llega a superar a la de residencia rural. Entre los deportados constituye el 68.4%.

Al considerar las regiones, en la ENADID, se notan diferencias muy marcadas, ya que mientras la regiones del Valle de México y de la Frontera tienen porcentajes bajos de migrantes rurales (32.1% y 34.2%, respectivamente) en las otras la proporción es mayor de 60%, especialmente en la de las Seis Entidades que alcanza 70%.

Escolaridad de los migrantes

Igual que sucedía en los aspectos antes mencionados, y siguiendo la tendencia de la población mexicana en su conjunto, ha aumentado el nivel de escolaridad de los migrantes. Sin embargo, y seguramente relacionado con el peso de la población rural, el porcentaje de analfabetismo continúa siendo bastante elevado y el promedio de escolaridad bajo.

Los datos de la ENADID nos muestran que únicamente el 4% de los migrantes no lee ni escribe; sin embargo, de los que asistieron a la escuela, más de la mitad (57.8%) no pasó más allá de la primaria y sólo 3.8% llegó a cursar estudios de nivel profesional. Según los datos de la EMIF, entre los que vienen de Estados Unidos, el porcentaje de los que no aprobaron ningún año de escuela es bastante alto, 11.7%, siendo bastante inferior en los deportados, 8.2%. De este mismo flujo, 53.6% no llegó al nivel de secundaria y sólo 1.1% llegó a aprobar grados de formación profesional.

Llama la atención que, en términos generales, las mujeres presentan niveles ligeramente superiores de escolaridad, ya que de las que no llegaron más allá de la primaria el porcentaje es de 57.8% (frente a 58.7% de los hombres), en tanto que en el nivel profesional presenta un 5.5% frente a un 3.4% en los hombres). En el flujo de los que regresan de Estados Unidos (EMIF) sucede algo semejante, ya que 11.8% de los hombres no llegó a aprobar ningún grado de escuela, frente a 4% de las mujeres. Unicamente 32% de los hombres pasaron más allá de la primaria, de las mujeres, 41.4%.

Sorprende el bajísimo nivel de escolaridad de la región I ya que 19.1% de los que nacieron ahí no terminó ningún grado escolar (de los nacidos en la región de la frontera, sólo 3.8%), y únicamente 17.3% llegaron a un nivel superior a la primaria (52.3% de la región II). Las diferencias son mucho menos pronunciadas entre la población rural y la urbana pues, por ejemplo, el porcentaje de los que no aprobó ningún grado fue de 13.1% en la población rural y de 11.2% en la urbana.

Si consideramos el promedio de años de escolaridad tenemos que en el flujo de los que vienen del sur de la EMIF[10], es de 5.96 en la población rural, y de 7.02, en la de origen urbano. En el caso de los que regresan de Estados Unidos, es de 5.41 y de 6.47, respectivamente. Entre los deportados es de 6.87 en los de origen urbano y de 6.16 en los de origen rural.

En cuanto a la escolaridad por sexo, observamos también que el de las mujeres es superior, 7.61, frente a 6.26 en los hombres en el flujo procedente del sur; de 7.09, frente a 5.9, en el que proviene de Estados Unidos y de 6.88, frente a 6.53 en los deportados. Así, parece comprobarse que las mujeres que migran son más preparadas, a pesar que, en el conjunto de la población ellas se encuentran en gran desventaja educativa frente a los varones.

Actividad laboral de los migrantes en México[11]

Actividad laboral por sexos

De acuerdo a la información de la ENADID, 78.6% de los hombres entrevistados trabajaron durante los 30 días anteriores al levantamiento de la encuesta. De los que no laboraron, fueron los que tenían empleo y no trabajaron, quienes alcanzaron

el porcentaje más alto (34.2%); sin embargo, la proporción de los que buscaban empleo era bastante elevada, 27.3%.

De los que venían voluntariamente de regreso de Estados Unidos (EMIF), e informaron al respecto, 83.9% trabajó los treinta días anteriores a su viaje a Estados Unidos y de los deportados, 78.7%. Así vemos que, como se ha señalado en muchas ocasiones, la migración no puede ser atribuida a la falta de empleo, sino a las diferencias en las remuneraciones.

De los que sí estuvieron ocupados, según la ENADID, el porcentaje más alto es el de los empleados u obreros con 44.7%; siguiéndolos en importancia los trabajadores por cuenta propia (30.9%) y los jornaleros (15.5%). Como se ve, aún cuando muchos de los migrantes siguen residiendo en áreas rurales, son muy pocos los que todavía laboran en actividades agrícolas. Aunque hay que tomar en cuenta que muchos de los trabajadores no remunerados (6.3%) y varios de los que señalaron ser trabajadores por cuenta propia podrían también laborar en el campo, en el predio familiar, los primeros y como ejidatarios o minifundistas agrícolas, los segundos. Sin embargo esta información no nos la proporciona la encuesta. Es de señalar que únicamente un 2.4% se ocupa como patrón o empresario, lo que resulta congruente con lo que se conoce de la práctica migratoria y del tipo de trabajos que realizan los mexicanos en Estados Unidos.

En lo que se refiere a los que venían voluntariamente de Estados Unidos (EMIF), más de la mitad (54.9%) se ocupó en el sector agropecuario; en los deportados el porcentaje es más bajo, pero superaba, de todos modos, a los demás (35.5%). Los otros sectores tenían mucho menor importancia en los retornantes voluntarios, 25.4%, el industrial (de los cuales el 17.3% correspondía a la industria de la construcción); y 19.6%, el terciario (0.2% correspondía al servicio doméstico). Entre los deportados, el sector industrial se acercaba más al agropecuario con 33.9% (20.5% en la construcción), muy cercano, también, al sector servicios, con 30.5% (1.1% en el servicio doméstico). Así vemos que, mientras el sector agropecuario tenía un importante peso entre los que regresaban voluntariamente, entre los deportados las actividades que se pueden considerar "urbanas" en conjunto superaban al sector primario.

Es de subrayarse la elevada proporción de migrantes ocupados en la construcción —en los de retorno voluntario alcanza 16%— frente a las demás subramas de la actividad industrial que sólo representan 8.6%. Esta situación nos hace pensar que la mayor parte de los que cuentan con empleos en el sector manufacturero no migran, mientras que, para los trabajadores de la industria de la construcción, la migración resulta una estrategia atractiva, sobre todo si tomamos en cuenta la inestabilidad del empleo en esa rama y las malas condiciones laborales y salariales que privan en ella.

De las mujeres, según la ENADID, la proporción de aquéllas que trabajaban en México es muy baja 32.5%. Cuando revisamos las causas nos damos cuenta que

se debe, en el 85% de los casos, a que se ocupaban en quehaceres del hogar. Sin embargo, hay que recalcar que todas ellas migraron a Estados Unidos con la finalidad de trabajar o buscar trabajo.

De las que sí estuvieron ocupadas, el porcentaje más alto es el de las empleadas u obreras con 68.8%. Les siguen las trabajadoras por cuenta propia (21.4%) y, con mucha distancia, las trabajadoras no remuneradas (7.2%). En cambio, el peso de las jornaleras es mínimo (2.2%).

Entre las que retornaron voluntariamente (EMIF), el porcentaje de las que trabajaban antes de ir a Estados Unidos[12] (38.9%), es ligeramente más alto que el de la ENADID, pero inferior al que presentan aquéllas que fueron deportadas (45.9%). Una proporción importante se ocupaba en el sector servicios, de las primeras, 68.2%; de las deportadas, 63.9% (16.7% y 19.8%, respectivamente, en el servicio doméstico). El sector industrial es el que presenta el peso más bajo en las de retorno voluntario, 7.6% ; en tanto que en las deportadas, el sector agrícola (14.9%).

Actividad por región de residencia

Naturalmente la situación cambia cuando consideramos la localidad de residencia, aunque en el caso de la actividad agropecuaria no resulta tan marcado como podría esperarse, ya que, en los de retorno de Estados Unidos, en las áreas rurales es de 61.4% y en las zonas no rurales, de 43.3%. En cambio, el sector industrial, sí muestra una diferencia considerable: 33.9% en las localidades urbanas frente a 20.6% en las rurales. En el sector terciario, aunque sí hay diferencias, éstas son menos notables (18% en las áreas rurales frente a 22.8% en las urbanas).

En la ENADID, observando únicamente el comportamiento masculino, los porcentajes más altos de obreros o empleados se encuentran en las regiones más urbanizadas, la región II y la región IV (53.1% y 51.6%, respectivamente), en tanto que en las regiones de mayor tradición migratoria (la región I y la región III), la proporción de jornaleros o peones es relativamente más alta (19,6% y 16%, respectivamente; frente a 7.2% en la región IV%). Llama la atención la elevada proporción de trabajadores no remunerados en las regiones III y V, ya que son de 13.2% y 10.4%, respectivamente, proporciones muy cercanas a las que ocupan los jornaleros. Quizá esto se deba a que en esas regiones es donde tiene mayor importancia la agricultura campesina de autoconsumo. Estos planteamientos se comprueban cuando analizamos el tipo de localidad en donde viven los migrantes, puesto que, en el caso de las ciudades de más de 100,000 habitantes, el porcentaje de empleados u obreros es de 64.5% (en las de 20,000 a 99,000, de 55.3%); en tanto que el de jornaleros es de 30.1% en las localidades de menos de 2,500 habitantes

frente a 2.3% y 6.2% en las de 20,000 a 99,000 y en las de 100,000 o más, respectivamente. Los trabajadores sin remuneración destacan en las localidades más pequeñas (14.9%); bajando su importancia a medida que se trata de asentamientos mayores. Por último, la proporción de trabajadores por cuenta propia es muy semejante en todos los tipos de localidades, aunque es un poco menor en las de 100,000 habitantes (28.7%).

En los deportados, el nivel de ocupación es alto en todas las regiones, superior a 70% ; especialmente elevado en la región del Valle de México (IV) donde alcanzó 87.6% y en la de Oaxaca-Guerrero (81.1%). Contrariamente a lo que se sabe con relación a la ocupación en la República Mexicana, fue la región fronteriza la que alcanzó el nivel más bajo de empleo (74.4%). Esto podría atribuirse a que muchos de los migrantes que viven ahí, lo hacen con la finalidad de pasar al otro lado, y no les interesa conseguir empleo. Un porcentaje relativamente alto de ellos, señaló que buscó trabajo y no encontró o que no trabajó por diversas razones.

De los ocupados, sobresalen, en el sector primario, la región I (49.3%), la región III (47%) y la región V (45%); en tanto que en el sector servicios destacan la región IV (38.9%) y la región III (36%). Por último, el trabajo en el sector industrial tiene el mayor peso en la región III (47.5%) y en la región IV (39.6%).

En el flujo de los que retornan voluntariamente, los porcentajes más altos en el sector agropecuario corresponden a las mismas regiones (I, III y V), pero en este caso las proporciones son superiores (61.3%, 62.4% y 68.1%). También, al igual que en los deportados, el sector servicios tiene un peso importante en la región IV, 42%, con lo que supera a los demás sectores económicos. En todas ellas el sector de la construcción supera al industrial (que presenta porcentajes bajísimos en todas las regiones) y es especialmente elevado en las regiones II y III.

En el caso de las mujeres (ENADID), en todas las regiones encontramos el alto nivel de desocupación, especialmente en la de las seis entidades donde alcanzó un porcentaje de 73.1% (la proporción más baja fue en la de Oaxaca-Guerrero con 63.7%). La proporción más elevada en cuanto a motivos de no laborar es la que corresponde a los llamados quehaceres del hogar, estando en los extremos la región III con 64% y la región IV con 49.7%. Esta última destaca por presentar un porcentaje muy superior de mujeres que buscaron trabajo (8.8%) y de estudiantes (6.9%). Por último, las que buscan trabajo se concentran en las ciudades de más de 100,000 habitantes, habiendo porcentajes mínimos en las menores de 20,000. En lo que se refiere a su participación en la actividad agrícola, quedan en los extremos la región de las seis entidades (III) donde sólo participan 26.9% y la de Oaxaca-Guerrero (V) con 36.3%. Estos datos llaman la atención, puesto que, las dos regiones presentan elevados porcentajes de población rural, lo que haría suponer un comportamiento semejante.

Se sabe, gracias a las investigaciones en microrregiones, que en esas zonas existen pocas posibilidades de empleo fuera del hogar, lo que se confirma en esta encuesta. Son las mujeres de las áreas urbanas las que más realizan trabajos fuera de su hogar, 38% de las que viven en localidades de más de 100,000 habitantes y 33.5% de las de ciudades pequeñas. En tanto que de las que viven en localidades de menos de 20,000, sólo lo hacen 26.3% y en las menores, 27.2%.

Como ya decíamos el peso más importante en la ocupación es el de empleadas u obreras, y sorprende que estén en los extremos las de la región fronteriza y la del Valle de México (74.6% y 52.9%, respectivamente), puesto que se trata de las regiones más urbanizadas. Es muy probable que la diferencia se deba a la existencia de las empresas maquiladoras de la frontera que ocupan a un elevado número de mujeres. Prácticamente no hay jornaleras (con excepción de la región fronteriza en la que se registró un 6.3%, lo que es atribuible a la agricultura comercial que emplea un elevado número de trabajadores agrícolas, aunque muchos de ellos son estacionales). Por último, la región donde predominan las mujeres trabajadoras sin pago, no es una de predominancia rural, sino la del valle de México donde el porcentaje alcanza el 38.6%.

Características de la actividad migratoria

Tradición migratoria

Los entrevistados de las dos encuestas reportan haber participado en la migración desde antes del Programa Bracero, aunque resulta difícil conocer su peso real, ya que gran parte de los que vivieron esa experiencia han muerto o, en menor medida, se han ido a vivir a Estados Unidos y, en el caso de la EMIF, pasaron la edad en la que es usual migrar. Es por ello que las proporciones de entrevistados en esas condiciones son muy bajas y únicamente nos ofrecen indicios de la importancia de esa actividad en las distintas regiones. Así podemos observar, como también se mencionó antes, que el peso de cada una de ellas ha ido variando.

A diferencia de lo que las investigaciones revisadas señalaban sobre la participación en la práctica migratoria de las distintas entidades federativas, según la información de la ENADID, antes de la firma del convenio para la contratación temporal de braceros (1942) los estados que tuvieron mayor participación son Tamaulipas y Durango, el primero contaba con 41.5%[13] de los que viajaron en ese período. De la región tradicional, sólo Michoacán destaca, aunque se ubicaba en tercer lugar seguido de San Luis Potosí y Nuevo León. Sin embargo, se trata de pocos casos —dada la antigüedad del evento— aunque no deja de llamar la atención. Durante el período del Programa Bracero, los estados fronterizos pierden peso y se colocan en los primeros lugares Michoacán y Guanajuato, seguidos por Nuevo León y Durango. Jalisco comienza a destacar en los 1970s, cuando se ubica en

primer lugar seguido por Michoacán, San Luis Potosí y Zacatecas. Es sólo en los 1980s cuando Jalisco adquiere importancia, ya que de los que migraron por última vez, los provenientes de ese estado constituyen el 16% en 1980-85 y el 19.2% en 1986. Sin embargo, no llega a superar a Michoacán que aporta el 22.6%. La región I tuvo su mayor predominio entre 1965 y 1986, ya que aportó el 46.8% de los migrantes. Si la unimos con la región III tenemos que el 70% de los que estuvieron por última vez en ese período provenía de esa zona; en tanto que las regiones IV y V sólo aportaron el 4.6% y el 4.5%, respectivamente.

En los que retornan voluntariamente (EMIF), al revés de lo que ocurría entre los informantes de la ENADID, la región I supera a las otras desde el primer período (con excepción al quinquenio de 1965-69) período en el que la región III le duplica en cuanto a presencia. Después de entonces su importancia resulta indiscutible hasta los 1990s donde su margen de ventaja se reduce notablemente, otra vez frente a la región III. Esta última es la que le sigue en todos los períodos, en tanto que en el tercer lugar se ubica la región de la frontera, excepto en el período 1965-69, cuando la del Valle de México se ubica en el tercer lugar.

Entre los deportados, la participación de las cuatro primeras regiones es muy semejante en el período anterior a 1941, destacando la de la zona fronteriza y la del Valle de México. En cambio, durante la época del Programa Bracero, sobresalen la de las seis entidades y la de Oaxaca-Guerrero. Así, según estos datos, la región I tampoco sobresale, lo que sólo ocurre a partir del período 1965-69, con 52.9%, justo al revés de lo que se observaba en el otro flujo. En los 1970s aporta 40% y su predominio se mantiene hasta 1986 con 35.6%. Después de entonces, vuelve a perder peso, con sólo un 27.7% de los migrantes; proporción ligeramente inferior a la de la región de la frontera (que cuenta con el 27.8%). Con los datos presentados, nos damos cuenta que es difícil saber a tantos años de distancia cuales eran las regiones preponderantes, aún cuando queda claro que son las tres primeras las que, en casi todos los casos, se ubican en los primeros lugares.

Por otro lado, según la información tanto de los que regresan de Estados Unidos, como de los deportados, la participación de la población rural fue muy importante durante los 1940s, 1950s y 1960s de más de 75%, bajando a partir de entonces, de manera que para la década de los noventas únicamente aportó el 50.6% en los de retorno voluntario.

Lugares de destino

De acuerdo a la EMIF, en el flujo de los de retorno voluntario, destacan, como era de esperarse, Texas con 39.6% y California con 30.1%. Les siguen en importancia, con una diferencia notable, Arizona con 5.1%, Florida con 3.3% y Carolina del Norte con 2.3%.

En cuanto a las ciudades, sobresalen, San Antonio y el Valle de Texas, con 6.9% cada una, Los Angeles, California con 6.2%, Houston y Dallas-Fort Worth en Texas con 4.4% y 4.2%, respectivamente y Fresno, California, y Phoenix, Arizona, con 3% y 2.9%, respectivamente.

Entre los deportados, el 81.9% sólo estuvo unas cuantas horas, por lo que únicamente tenemos información del lugar de destino en 18.1% de los casos (88,498, ya que, además, hubo 1,051 individuos que no informaron). Sin embargo, coinciden en la mayoría de los estados de destino, aún cuando no en las proporciones, lo que está relacionado, quizá, con su situación más inestable, la importancia de las zonas por donde entran, y la falta de tiempo para adentrarse más en el país. En lo que respecta a los estados, California ocupa el primer lugar con 44% de los migrantes; Texas, el segundo, con 31.9% y Arizona, el tercero, con 12.7%. El cambio de orden coincide también con lo que encontramos en la primacía de las ciudades, ya que, aunque la ciudad que tiene mayor peso es Los Angeles (7.9%), las ciudades que la siguen muy de cerca son las fronterizas de Phoenix (7.3%) y San Diego (7.2%). Después vienen el Valle de Texas (5.1%) y otra fronteriza, El Paso, Texas (4.7%).

Es probable que esta información resulte sesgada —sobre todo en el caso de los deportados— hacia las ciudades y los estados fronterizos, ya que los que logran interiorizarse en el país, tienen mayores posibilidades de no ser expulsados y de regresar por avión directamente al interior de México. Y es que parece ser que los que llegan a los estados del centro o del norte de Estados Unidos obtienen mejores remuneraciones y permanecen por períodos de tiempo mayores, por lo que cuentan con más recursos para viajar en avión y así evitarse el problema de dirigirse a la frontera y de ahí a sus lugares de origen.

Como ya ha sido señalado en otras investigaciones, la preferencia por cada estado varía por regiones y por entidades de origen de los migrantes, situación que se encuentra muy relacionada con la existencia de una tradición migratoria y de redes familiares de los dos lados de la frontera.

Aunque en todas las regiones predominan California y Texas, la proporción y el orden varían en cada caso. En el caso de los que retornan de manera voluntaria (EMIF), en la región I y la región V sobresale California, con 37.8% en la primera y 63.5% en la segunda; seguidos por Texas con 30.5% y 10.1%, respectivamente. En las otras tres, Texas atrae una mayor población, especialmente en la región IV y la región II, con 60.7% y 60.6% de sus migrantes, respectivamente, en tanto que California sólo atrae a 16.1% y 11.6%, respectivamente. En la región III, aunque Texas supera a California, el margen entre ellos es mucho menor (37.8% en el primero frente a 27.5%, en el segundo). Los demás estados, presentan mucho menor concentración.

En las regiones de mayor tradición, los migrantes se encuentran más repartidos en las ciudades. En la región I, principalmente en San Antonio, Texas (7.5%);

Fresno, California (5.6%) y el Valle de Texas (4%). En la de la frontera, únicamente poblaciones texanas: el Valle de Texas en primer lugar con 8.7%, seguido por Houston (6.5%), El Paso (5.8%), Dallas-Fort Worth (5.5%) y San Antonio (4.8%). En la de las seis entidades existe más concentración en el Valle de Texas (12.7%) y Los Angeles (12.1%), que superan con mucho a ciudades como Dallas-Fort Worth (4.6%), Phoenix, Arizona, (4.5%) y San Antonio (4%). Los procedentes de la región IV y la región V presentan mayor concentración: los del Valle de México, en San Antonio (18.4%) y, en menor medida, en Houston (8.7%) y, los de Oaxaca-Guerrero, en Los Angeles (18.5%) seguido, con mucha distancia, por Fresno, California (7.1%).

En el caso de los deportados, no se logra apreciar suficientemente este fenómeno por los motivos relacionados con su expulsión, señalados anteriormente. Para los de la región de mayor tradición migrante, California destaca con una alta proporción (61.6%) seguido con un amplio margen de diferencia por Texas (24.2%). En la región III, también es California el estado preferido (32.8%), pero seguido muy de cerca por Arizona (27.6%) y Texas (27.3%). Como sucedía con los del flujo de migrantes voluntarios, en la región fronteriza, Texas es la principal fuente de atracción (53.5%). En las regiones IV y V, California es el polo principal, especialmente en la región V, ya que el 76.2% de sus migrantes, se dirigió a ese estado.

Número de viajes y duración de las estancias

De acuerdo a la ENADID, de los migrantes de retorno, 68.1% permanecieron en Estados Unidos menos de un año durante su última estancia. Sin embargo, hubo 12.6% que habían estado dos o más años. En cambio, y como era de esperarse, de los que estaban en Estados Unidos cuando se levantó la encuesta, 42.5% llevaban en ese país 2 años o más, aún cuando seguían manteniendo nexos con su familia de México, que los reconocía como parte del grupo.

En cuanto al número de viajes a Estados Unidos para trabajar, en los migrantes que retornaron voluntariamente, captados por la EMIF, el 34.3% sólo lo había hecho una o dos veces y 18.4%, de 3 a 5; pero un porcentaje relativamente alto (34.2%) señaló que lo había hecho más de diez veces. La situación es muy diferente en el caso de las mujeres, ya que únicamente 13.6% de ellas había ido a trabajar 11 veces o más, en tanto que casi 80% viajaron menos de seis veces.[14]

De los deportados, para el 53.6% de los casos era la primera vez que lo habían hecho; y, de los restantes, 23.8% sólo había cruzado entre una y dos veces más, sólo un 5.8% que fue 11 o más. Así pues se aprecia que, en términos generales, los deportados tienen menos experiencia en la práctica, aún cuando hay quienes a pesar de haber estado en Estados Unidos varias veces, resultan ser deportados.

Períodos de entrada a Estados Unidos y de salida

Como es bien sabido, el flujo migratorio varía a lo largo del año, siendo los primeros meses, aquéllos en que se concentran más emigrantes, en tanto que los que regresan lo hacen preferentemente en los últimos meses. Esta situación tiene su explicación, tanto en los requerimientos de la agricultura comercial norteamericana y las inclemencias del tiempo, como en la tradición que se ha impuesto en las comunidades de migrantes, de reunirse y hacer sus celebraciones locales (principalmente las fiestas de Navidad y de los santos patronos de los pueblos) y familiares (bodas, sobre todo) en los meses de diciembre y enero. Esto se comprobó en las encuestas revisadas, aún cuando todos los meses del año se presentan salidas y regresos. De acuerdo a la ENADID, los porcentajes de emigrantes se van reduciendo en cada trimestre, según la información aportada sobre la fecha del último viaje. 29.7% en el primero (enero-marzo); 28.4% en el segundo (abril-junio), 27.1% en el tercero (julio-septiembre) y 14.9% en el cuarto (octubre-diciembre). En cuanto al retorno, sucede exactamente lo contrario, 14% en el primero; 21.1% en el segundo; 29.6% en el tercero y 35.3%, respectivamente.

Actividad laboral en Estados Unidos

Un elevado porcentaje de los que regresaron voluntariamente, sin contar a los que permanecieron horas (3.5%) consiguió trabajo en Estados Unidos, 88.8% (88.9% de los hombres y 87.1% de las mujeres).

A pesar de que mucho se ha comentado, y se ha detectado en investigaciones microrregionales que la agricultura ha perdido importancia en la actividad económica de los migrantes, en el flujo de los que vienen de regreso, el sector agropecuario seguía siendo el que ocupaba a más de la mitad (52.7%). Asimismo, notamos que, a pesar de que se ha señalado al sector servicios como el predominante; en la encuesta es el sector industrial el que sigue en importancia con 24.6%. Llama la atención, que, al igual que sucedía en la actividad laboral en México, en Estados Unidos también tiene un importante peso la industria de la construcción, ya que casi dos terceras partes (16%), de las personas ocupadas en la industria, se emplean en esta actividad. Al último se encuentran los servicios con 22.7% (5.8% en el servicio doméstico).

Conviene señalar la especificidad de la actividad laboral de las mujeres, aunque se trata de un grupo reducido —8768, que constituyen el 1.9% de los migrantes que trabajaron e informaron sobre su actividad laboral en Estados Unidos)— ya que resulta muy diferente a la de los hombres. El porcentaje más alto de ellas laboró en los servicios, 62.6%, de las cuales, más de la mitad lo hizo en el servicio doméstico (33.9%). Seguía en importancia el sector industrial con 28.7% (únicamente 1.8% en la construcción) y, sólo 8.7% se empleaba en actividades

agropecuarias. El hecho, ya señalado en otras investigaciones, de la importancia que tiene el servicio doméstico en la población femenina, aquí queda sobradamente demostrado. Además, un porcentaje mucho más alto que el de los hombres, se ocupa en la industria, lo que también hace pensar en que varias de ellas se ocupan en establecimientos dedicados a la confección de ropa o al ensamblado, aunque no es posible saberlo con exactitud.

Como ya se dijo, los deportados, muy pocos deportados lograron trabajar e informaron al respecto (46,204); sin embargo, observamos en ellos una distribución muy diferente: el sector en el que más se ocuparon fue el de los servicios, con 47.6%, de los cuales 12.4% trabajaba en servicios domésticos. La agricultura sólo alcanzó 32.1%; mostrando en el porcentaje más bajo los que laboraban en el sector industrial (20.2%, de los cuales el 14.7% se ocupaba en la industria de la construcción). La gran mayoría de ellos estaba empleado a sueldo fijo, especialmente los que se ocupaban en el sector industrial (85.9%), en tanto que de los que trabajaban en la construcción y el servicio doméstico, alrededor de una tercera parte trabajaba a destajo o por obra determinada.

Si consideramos el tipo de localidad de residencia en México de los migrantes que regresan de Estados Unidos, tenemos que, aunque en todos ellos sobresale la actividad agrícola, presenta un porcentaje mayor en los que provienen del medio rural (58%, frente a 46.6% en los urbanos), en tanto que en la industria manufacturera y en los servicios el peso de los de localidades urbanas es mayor.[15] En la industria de la construcción, presentan proporciones semejantes, aunque ligeramente superiores en los de origen rural (16.4% frente a 14.2%).

Hay que señalar que los porcentajes por ramas de actividad en Estados Unidos son muy semejantes a los que presentan esas mismas ramas en México, especialmente en lo que se refiere a los sectores primario y secundario; ya que en el caso de los servicios, es menor el porcentaje de los que se ocupan en esa rama en Estados Unidos (14.9% frente a 18.6%, en México) y, especialmente en el servicio doméstico (5.8% en Estados Unidos, frente a sólo 0.3% en México.

Por último, aunque existe cierta relación entre la actividad desempeñada en México y la que se realiza en Estados Unidos, ésta no es tan determinante, ya que únicamente 48.2% de ellos coinciden en la misma actividad en los dos mercados laborales. Sin embargo, son los que en su país de origen se ocupan en la rama agropecuaria los que en un porcentaje mayor laboran en esa rama, 67.1%; pero también presentan una proporción elevada los que en México laboran en el sector industrial (61.1%). En los servicios no sucede lo mismo, de los que provienen de esa rama en México, únicamente el 26.6% se ubica en el sector primario en Estados Unidos (y 20.4% de los que provienen del servicio doméstico).

En el sector industrial como actividad en Estados Unidos, el porcentaje más elevado lo tienen los que trabajaron en esa misma rama en México (13.8%), seguidos

por los que estuvieron en el sector servicios (12.1%). En cambio, de los que provienen del sector agropecuario, sólo 6.3% labora en esa rama de actividad. También en los servicios tienen mayor presencia los que realizan actividades de esa rama en México, 22.8%. Y, por último, donde existe una relación mayor es en el caso de los que en México se ocupan en el servicio doméstico, ya que el 79.6% de ellos también trabaja en esa actividad en Estados Unidos. La proporción de los que provienen de las otras ramas es sumamente baja.

Notes

1. Todos ellos citados por Ernesto Galarza (1958, 1964 y 1977).

2. La limitación del trabajo de Alarcón es que poco explica sobre migración documentada e indocumentada, número de viajes, duración de los mismos, tipos de trabajos, etc. Mucho menos trata de relacionar estas variables entre sí o con otras demográficas o económicas.

3. De ellos, había 18 migrantes en Estados Unidos, 17 jornaleros y uno con actividad no definida.

4. Incluye a las personas que tenían como mínimo 15 años, residentes habituales de la vivienda y que en el momento de la entrevista se encontraban en Estados Unidos trabajando o buscando trabajo y que tenían familiares que pudieran informar sobre ellas, y a aquellas que habían trabajado o buscado trabajo en Estados Unidos en los últimos cinco años (desde el 1o. de enero de 1974) y que se encontraban viviendo en México en el momento de la entrevista (CENIET, 1982).

5. Conviene aclarar que la información es diferente para los dos conjuntos de migrantes. Para aquellos que se encontraban en Estados Unidos, se refiere al trabajo que tenían antes de migrar, en tanto que para los que ya estaban en México, al momento de la entrevista: diciembre de 1978 o enero de 1979.

6. No explica sobre la edad de estos ejidatarios migrantes, ni cuando migraron por última vez.

7. En el caso de la agricultura, el 75% percibía ese salario, en la industria 62.5% y en los servicios, el 78.6% (Trigueros, 1994).

8. En el flujo de los migrantes que regresan a México de la EMIF, encontramos otro orden. Después de Guanajuato y Michoacán se ubican Chihuahua y Zacatecas. Jalisco queda hasta el quinto lugar. El estado de México y Guerrero presentan poca participación, en tanto que Coahuila ocupa el sexto lugar.

9. Llaman la atención por el gran peso de la población masculina, los estados del centro como Tlaxcala (86.3%), Querétaro (85.2%), de la región IV y Aguascalientes (86.6%), de la región III. Los estados de Sinaloa y Tabasco presentan la menor proporción, 63%.

10. La información sobre los promedios de escolaridad para el caso de la EMIF, fueron proporcionados por el Dr. Jorge Santibáñez del Colegio de la Frontera Norte.

11. En el caso de la ENADID, la información sobre la actividad laboral se refiere a los treinta últimos días antes del levantamiento de la encuesta y no a la situación que tenía el informante antes de viajar a Estados Unidos.

12. Hay que señalar que se trata de muy pocos casos, 3972.

13. Es probable que esto se deba a la situación fronteriza.

14. Hubo un 1% de los migrantes que señaló no haber ido nunca (la vez que cruzaron sólo estuvieron algunas horas).

15. En la industria (sin incluir a los de la construcción) los porcentajes son 10.1% en los de localidades urbanas y 6.6%, en los de origen rural. En los servicios, 29.1% (7.9% en servicio doméstico) en los primeros y 19% (3.5% en servicio doméstico) en los segundos.

Characteristics of Migrants

Some Thoughts on Perceptions and Policies Mexico-United States Labor Migration Flows:
Some Theoretical and Methodological Innovations and Research Findings

Jorge A. Bustamante

Introduction

Migrations between Mexico and the United States are associated primarily to the geographical vicinity of the two countries. There was a time when the concern for undocumented immigrants was in Mexico City in reference to the increasing number of U.S. citizens who were crossing the unprotected borders of Mexico to enter the states of Texas, California, Colorado and New Mexico without authorization of the Mexican government. A war resulted from that illegal flow and Mexico lost lands representing half of its territory. The ink of the Treaty of Guadalupe-Hidalgo (1848) had not dried out when migrations on the opposite direction began to increase. Labor migrations in massive numbers from Mexico to the United States were sought after by aggressive recruiters funded by the U.S. Congress in the first decades of the 20th century, in order to allow the economic expansion of

the United States southwest. U.S. recruiters of Mexican labor were restless at the beginning of the century in the states of Guanajuato, Jalisco and Michoacán, attracting Mexican workers for the expansion of railroads, the exploitation of mines and the opening of new lands for agriculture in the states of California, New Mexico, Colorado and Texas. These recruiting efforts funded by U.S. Congress at the beginning of the century gave birth to networks of Mexican migrants which even today explain the predominance of a small number of Mexican states in the totals of migrants who have interacted with continuous U.S. demands for Mexican labor shaping a *de facto* international labor markets between the two countries.

This labor market is not recognized as such by the two countries. International migration from Mexico to the United States is viewed very differently depending on the side of the border from which this phenomenon is observed and evaluated. It is difficult to demystify migration between Mexico and the United States, and to explain what it represents for each country. This is particularly the case with undocumented migration. Because of the contradictory visions of undocumented migration that permeate values and perceptions of the people of these two countries, an effort of demystification is indispensable if both nations really seek economic integration as it is assumed in the North American Free Trade Agreement (NAFTA)

The view that predominates in Mexico is that outmigration toward the United States is basically an economic phenomenon, a labor issue, from which the United States reaps the benefits since Mexican migrants fill jobs that U.S. workers are unwilling to take. Thus, the migrant workers are carrying out an activity which is as legitimate as the profits made by their U.S. employers.

In the United States, in contrast, the predominant view of these same migrants is that they are in the majority criminals, who transport drugs from Mexico and enter the United States to subsist on public assistance programs or to take jobs which rightly belong to U.S. citizens. Supposedly these U.S. workers are forced into unemployment by the influx of Mexican migrants who come to steal their jobs.

In Mexico these individuals are called “migrant workers” and they are viewed in such a positive light that their family members are openly proud of their achievements. In the United States, they are called “illegal aliens”; they are viewed in a very negative light, almost like a plague invading from outside and where the citizens of the United States are made the victims. Given the respective acceptance of these contrasting visions in the two countries, the migratory phenomenon also evokes contrasting perceptions in terms of how the set of migration problems interjects into the relations between the two countries. Mexico’s view of the problems associated with migrant workers encompasses things such as the violation of their human and workers’ rights abroad; this being the case, the Mexican government seeks a bilateral agreement that would eliminate such abuses. The United States’ view is that the primary problem associated with “illegal aliens” is their violation

of U.S. immigration law; this being the case, the U.S. government seeks a solution in anti-crime legislation, part of domestic legislation to govern domestic problems.

It is virtually impossible for these two visions, sustained respectively by the civil societies of the two countries, to be both correct. One of these two visions must not correspond to the reality of migration. One of these two visions contains more myth than truth, although it is very possible that neither of them captures the full range of cases. This fact makes it imperative to begin a process of de-mythifying migration as a necessary and sufficient condition that would allow both countries to come together within the context of bilateral relations and find ways to act jointly to address the impacts of the issue in both countries.

Such a de-mythifying effort must begin with scientific research which can help us develop a diagnosis of the costs and benefits that labor migration from Mexico to the United States brings to the two countries. The results of this diagnosis should stimulate a raising of consciousness on the reality of migration and stimulate a consensus in both countries regarding the need to eliminate undocumented migration through a bilaterally negotiated process that would have to be concomitant to a formal agreement on labor migration between Mexico and the United States.

For the de-mythification of migration to succeed in both countries, it is essential that efforts should be undertaken bilaterally by research institutions in both Mexico and the United States, institutions of such repute in the international scientific community that their conclusions would be credited even if they diverged from the visions predominating within the two countries' respective governments and civil societies.

This paper will attempt to lead the scientific communities of both Mexico and the United States to the conviction that a bilateral effort to de-mythify undocumented Mexico-U.S. migration is a first and necessary step, and that this first step may suffice to initiate a rationalization process that eliminates migration as an obstacle in the relations between these two countries. The complexity of the task involved in addressing and resolving the issue of migration within a context of bilateral relations is as great as it is the gap between the actual characteristics of migration and these characteristics as they are popularly perceived.

If our objective is to build a broad and shared understanding of migration, we must explain why the gap referred to above is so wide. Toward this purpose this paper is divided in three parts. The first part consists of a historical approach to the cultural and economic meaning of the Mexican migration to the United States. The second part consists of some recent findings from a research project designed to monitor the undocumented migratory flows from Mexico to the United States.[1] The third part consist of a policy proposal derived from the theoretical approach discussed in the first two parts.

The first two parts correspond to a conceptual dichotomy derived from Max Weber theory of Verstehende soziologie[2] (Interpretative Sociology). The first chapter of the posthumously published work of the German sociologist and, research findings reported elsewhere,[3] led to a methodological distinction between two dimensions of the phenomenon of Mexican immigration to the United States. One called here "cultural" and, the other called "interactional." This distinction is derived from empirical findings which show a relative independence of changes in U.S. public perceptions of Mexican undocumented immigrants on one hand; and, hiring practices by their U.S. employers as well as some economic consequences of the insertion of these migrants into the U.S. labor market, on the other.

It will be argued in this paper that, in periods of economic recessions, U.S. public opinion has gone to extremes of negative views about the presence of Mexican immigrants, whereas in periods of economic expansion public opinion has swung to less negative and even positive views praising Mexican labor.[4] These changes in U.S. public opinion have not impacted significantly the persistent growth of U.S. demands for Mexican immigrant labor over the century, as one could infer from data presented by Paul Taylor (1928, 1929a, 1929b, 1930, 1931a, 1931b, 1968, 1971); Manuel Gamio (1926, 1930a, 1930b); Ernesto Galarza (1956, 1958, 1964); Julian Samora (1970, 1971a, 1971b) and Bustamante (1975, 1977, 1978, 1979a, 1979b, 1979c, 1979d, 1982, 1983, 1984, 1988, 1989a, 1989b, 1990, 1992).

The importance of such a distinction is, that these two dimensions not only behave differently over economic cycles, but, they can not be approached for scientific purposes by the same research methods. What is called here the "cultural dimension," corresponds to an epistemological approach which draws from Max Weber's notion of "erklarendes Verstehen,"[5] one which datum is to be found in the cultural or intersubjective dimension of social relations. What it is called here the "interactional dimension" corresponds to a different epistemological approach which draws also from Weber's conceptualization of "direct understanding" (aktuelle Verstehen).[6] In this dimension of the phenomenon of undocumented immigration from Mexico, the more directly observable nature of its datum, allows for more complex levels of quantitative analysis. This is the level of statistical analysis that could be made out of actual identification and countings of migrants crossing the international border without inspection. The fact that there is an observable behavior that occurs under certain objective circumstances,[7] allows for a more complex quantitative analysis than the values or motivations based on which such a person makes some sense out of such a behavior.

The nature of the datum for an analysis of such values or motivations is less ready for a direct observation with the instruments currently available for the scientific observer of such an individual's behavior. In other words, the difference between the "aktuelle Verstehen" and, the "erklarendes Verstehen" of the

undocumented immigration from Mexico can be illustrated by the difference between asking ourselves how many are crossing the border and, why they are crossing it. This difference does not allude to the scientific quality of the datum in one, versus the other dimension of reality. It alludes to the method of scientific analysis pertaining to one in contrast to the most appropriate for the other. Both basic datum are respectively, equally grounded in the empirical reality. They differ however, in its respective susceptibility of quantitative measurability and statistical analysis. Not because of difference in its empirical nature but because of the available scientific tools for the analysis of one in contrast to the other dimension.

This "cultural-interactional" dichotomy suggested here, is meant to be operational of the weberian concept of "verstehende Soziologie."[8] Such an operationalization is meant to emphasize a crucial epistemological distinction made by Weber between, a)the world of values, ideas, beliefs or myths, susceptible of a scientific understanding through a systematic procedure of "Verstehen" or interpretation rendered "adequate at the level of meaning" (Sinnhaft adaquat);[9] and, b) the world of directly observable behavior, more susceptible of being counted and thus, subjected to statistical analysis rendered adequate (Kausal adequate)[10] at the level of causal associations.[11]

The basic premise of the theoretical framework proposed here for the study of migration from Mexico to the United States is that this migration occurs within a context of interaction processes between people of two different countries and within a space which encompasses the two sides of the international border. This is especially true for undocumented migration. In general terms, Mexican migration to the United States can be conceptualized as the outcome of the interaction between U.S. employers and Mexican workers. This social interaction occurs within a labor market which is by nature international, because the actors who personify demand constitute a demand from within the United States, actualizing this demand when they hire undocumented migrants and; because the actors who personify supply do this from Mexico when they make a decision to migrate to the United States in search of jobs.

For this conceptual frame I continue drawing from the basic sociological concepts introduced by the sociologist of Erfurt. Beginning with the cultural dimension implied in the concept of "Gemeinter Sinn," it could be suggested that the social relations of migration between Mexico and the United States sprung out from the conceptualization of a certain option by the would-be migrant, that is, to migrate to the United States in search for a job. That option was taken because it was part of his or her culture. As such, it is learned in a process of socialization which is both a necessary and sufficient condition for the behavior that involves migration to the United States from some point in Mexico. That option and the corresponding behavior of migration would not be rational from the part of the

migrant if it were not for a corresponding behavior of a stranger in all cultural senses except one. That of the "Gemeinter Sinn" of a labor related interaction, which is shared by the would-be migrant from a distant place in one country, with a would-be-employer from another country. That would-be employer is some body with a different background and from a different country than the migrant who has also conceptualized an option: to hire a Mexican migrant. Such an option is also an element of his culture as it is shown below reflected in the quotations from Vice President Nance Garner and Senator McCarran respectively. The would-be U.S. employer has learned the socially constructed meaning of hiring a Mexican migrant as a part of a socialization process without which the social relations of migration between Mexico and the United States as we know them would not take place. That shared "Gemeinter Sinn" of a labor interaction is the necessary condition for the social relation of undocumented migration in which the Mexican actor and the American actors recognize their respective behaviors as mutually addressed to each other, as they become engaged in a social relation of labor giving birth to the micro dimensional instance of what we know as Mexican undocumented immigration to the United States. In the sharing of a "Gemeinter Sinn" of labor it is implied a complex dimension of history. A history of how such a meaning became an element in the respective cultures of the Mexican migrant and U.S. employer.

That historical dimension requires a special method of scientific inquiry which is different than the one it is required for the study of the interactional dimension implied in the actual experience of hiring and been hired implied in the phenomenon of the undocumented immigration from Mexico. In such an experience is where one finds the objective dimension of migration as a social relation. In this structural context the Mexican migrant embodies a labor supply that interacts and corresponds in a rational way to the behavior of the U.S. employer who embodies a labor demand. In the understanding of what this conceptual formulation implies, lies the theoretical understanding of undocumented migration from Mexico to the United States as a social relationship.

Theoretical Foundations for the "Interactional Dimension of a Labor Market"

The concept of "interaction" is understood here as it was used by Weber. The importance of this concept lies in how it relates to the concept of an "international labor market." I am not speaking here about the concept of "market" as it is used in classical and neoclassical economics, but in the sense that it is used by sociologists, and developed out of Max Weber's theory of social interaction.

In this theoretical context, Weber distinguishes between the idea of a "perfect market," which would resemble that understood by classical economic theory, and

the idea of an "imperfect market," which diverges from the assumptions of a perfect market. Weber's vision of an "imperfect market"[12] can be applied to structural conditions in which processes of interaction based on money exchanges occur between actors who tend to occupy differential or asymmetric power positions.

The primary difference between these two types of "market" lies in the fact that the "perfect market" assumes a relationship between actors that is sufficiently symmetrical to foster a dynamic that tends toward equilibrium between the elements in the relationship. I do not propose to determine whether this idea does or does not apply to the international labor market from which the phenomenon of undocumented migration from Mexico to the United States emerged. Rather, my objective is to use the concept of an "imperfect market" as developed from Max Weber's formulations for two reasons: First, this concept permits the introduction of the element of "power asymmetry" into the relationship between the principal actors of the "labor market," and second, it allows a virtual dissection of the interaction processes that make up this relationship. These processes range from the cultural elements that shape intentions in a reflective motion. Those elements which go, from what George Herbert Mead found in his notion of "mind" as a social construct at a microdimensional level of analysis, to the macrodimensional levels of the interactions between the economies of the United States and Mexico through the process of labor migration, including the objective elements that characterize international migration, such as an exchanged labor relationship for money.

Levels of Analysis

Within this theoretical context, undocumented migration from Mexico to the United States is understood as a phenomenon that occurs within a) the respective cultures of the actors involved which implies a historical dimension of the migratory phenomenon and, b) the structure of an international labor market that spatially extends to cover both sides of the border. Interactions occur at various levels within this structure. The most important is the interaction that takes place between a labor demand, personified by U.S. employers, and a labor supply, personified by Mexican migrant workers. We speak of the personification of supply and demand because both supply and demand include "structural conditions" that go beyond the behavioral interaction between an individual employer and the worker he employs.

Another level at which these processes of interaction occur involves the interaction between the "structural conditions" of demand and the "structural conditions" of supply in the country where the migration flows originate and the country that receives them. The term "structural conditions" refers here to somewhat abstract notions, such as the state of the respective national or regional economies or, the respective national states, as either of them become imposed on the

international labor market outcomes. That labor market is where the Mexican migrants and their U.S. employers interact. These "structural conditions" are operationalized respectively as "factors." These are the set of elements ("factors") that comprise everything causally related to labor demand or labor supply, including migratory behaviors. Hence, the term "factors" refers to the elements that make up labor demand and labor supply in the international market in which migrants participate. It is the "factors" that allow or make possible or necessary the presence of a labor supply or a labor demand. The set of "factors" that makes up the "structural conditions" of labor supply may be partially or totally independent from the "factors" that make up the "structural conditions" of labor demand.

An Operationalization of the Levels of Analysis

Although we can envision other levels of interaction—to explain cultural influences or changes, for example—for the research that I propose here, only three levels of analysis need to be used; these are outlined below:

A) The level of interaction between specific actors, where we seek to explain their observed and inferred behavior and behavioral change. Each of these actors directs or orients his behavior toward the other in a relationship that exists because both actors share or understand in the same way the meaning of the other's behavior. In the case of the migrants of one country and the employers of another country, the interaction is a labor relation, that is, a relation in which both actors understand that one will provide labor and the other will pay money in exchange.

This theoretical context assumes that there may be power asymmetry between the actors in the interaction, and that this power differential determines asymmetric positions for the actors within the structure of market relations. Given this assumption, we can design the research to empirically identify what are the defining characteristics of the power asymmetry between actors, and what are the implications of this asymmetry for the nature of the relationship.

At this level, the interaction between actors can be extended to include interactions between migrants and other actors who are on the demand side but are not strictly employers. These are called "significant others." An illustration of these are the agents of the United States Border Patrol or representatives of other organizations or institutions on the demand side, who interact so frequently with the migrants that enable the observer to empirically identify patterns of interaction.

One important methodological characteristic of this level of analysis is that it can be carried from the macrodimentional levels to the most microdimensional ones that the research demands. This was probably one important reason why Weber placed the definition of basic concepts for the study of social relations in the first chapter dedicated to spell out the methodology that would correspond to his theoretical approach. More important for the purposes of this paper is to underline the theoretical difference between the notion of market in classical economics and the notion of market in the sociological theory of Max Weber. This is especially important when the object of our study is a labor market. We sociologists object to equating labor with the purchase or the bartering of a barrel of oil or a ton of corn, as if all can be equated as market commodities. To the extent that the labor force as a commodity is linked with the destiny of its producer in terms of universally accepted human and labor rights, it is significantly differentiated from any other type of commodity. Because these other commodities have no inherent rights associated with their producer, they can have, and in fact do have, a destiny that can be totally independent of that of their buyers or sellers. Because of their independent destiny, these commodities are generally subject to markets in which price, theoretically is the result of a tendency toward an equilibrium between the forces of supply and the forces of demand. This tendency could not be assumed without some minimum degree of power symmetry between the actors representing supply and demand respectively. When we turn to look at a labor market from a sociological perspective, it is virtually impossible to find such symmetry and equilibrium, particularly as we look at the lowest wage levels. This is why Weber diverges from the notion of market proposed in classical economics in order to introduce the variable of power as an element in the interactions of an "imperfect market," a concept particularly applicable to labor markets. Here power is taken to mean the number and merit of the options that each partner in the labor relationship has to impose its conditions on the other partner.[13]

According to adherents of Weber's theory of social relations, the idea of labor market stems from the premise that it is a social structure shaped by interactions between actors who can hold differential power positions; thus, the exchange of labor for money need not necessarily tend toward equilibrium for us to be able to view it validly as a market relationship. Weber introduces the element of power differential between actors in an "imperfect market," and we can use his sociological construct in modeling a labor relationship as asymmetric, such as the one that exists

between Mexican migrant workers and U.S. employers. Weber's concept of market permits us to logically organize not only the specific elements that personify supply and demand, but also the contexts that condition the existence of supply and demand, respectively, as components of this market. Thus, this is how this concept allows us to speak of the "structural conditions" on the "demand side" and on the "supply side." These conditions include "factors" such as the domestic market of each country, allowing us to envision the interactions of each domestic labor market with that of the neighboring country through the link of international migration. This means that each domestic labor market is a part of the respective conditions of supply and demand in the context of an international labor market. This is the theoretical notion that it is used here in order to understand the processes of interaction between factors located on both sides of the frontier between the two countries interconnected by this migration. These factors produce impacts on a phenomenon whose empirical reality can be defined by the fact that migrants sell their labor in exchange for money in a country other than their homeland.

B) The level of interaction between the "structural conditions" that correspond to supply and demand, respectively. This is a level of analysis that permits a more macrodimensional focus, through which it is possible to analyze, for example, the interactions between a state of economic recession on the demand side and a drop in the amount of remittances that migrants make to their home economies. Another example might be the interaction between changes in the age structure of the population on the demand side, when these changes yield a labor shortage that interacts with conditions on the supply side to produce a migration flow that has different conditions than it would have had if there were no changes in the age structure on the demand side.

C) The level of interaction between the "factors" that comprise the "conditions" of supply or of demand in such an international labor market. By focusing the analysis at this level, it is possible to move from the macro to the micro level in order to examine the relationship that could exist, for example, when drought affects a region in the migrants' country of origin, increasing their need to depend on work in the United States. The resulting increase in the migrant labor force, in turn, lowers the "market value" in the United States of those migrants who were the victims of the drought in their home region.

In the scenario proposed above, we could say that drought in the region of origin entered into interaction with the demand conditions in the destination country

through the phenomenon of migration, even though this drought would have been an independent factor with respect to the demand conditions if migration did not exist as a mediating link between the two countries. This same concept of migration as a mediator, enabling conditions of supply in one country to interact with conditions of demand in the other, allows us to identify and measure the costs and benefits of undocumented migration for the sending country and for the receiving country, as well as the association between them. This is something that would be very difficult to do without this concept. It explains, for example, the inflation that occurs on the supply side when the migrants make seasonal returns to their homes in Mexico; and, on the demand side the social mobility of some Hispanics as a result of the savings that the hiring of undocumented Mexican migrants represents.

The theoretical schema presented above refers to a relatively static view of the structure of relations in an international labor market. Therefore there must be other concepts that can contribute toward explaining the dynamism that actually characterizes the migration phenomenon. Along this line of thinking the concepts of "circular migration," "migration flows," and "migration stocks" will be introduced after the following section.

The main objective of this paper is to make clear, through scientific methods, the elements that turn the reality of migration between Mexico and the United States into a myth, and the elements that hinder our understanding of this reality. Only with a clear understanding can the people and the governments of these two countries act in concert to address the migration issue in a way that takes their respective interests into account.

With this aim in mind, a central definition of undocumented immigration is proposed. One that could be used to lead scientific research as well as serving as a common ground for bilateral negotiations.

A Central Definition of Undocumented Immigration from Mexico

Undocumented immigration from Mexico to the United States is understood here as a process of social interactions between people from the two countries as they move across the U.S.-Mexico border or are located in a country different than that of his or her counterpart in a labor relation. The basic meaning of these interactions corresponds to an international labor market where the demand from the United States is as real as the supply from Mexico.

The basic elements of this definition are the concepts of a) a context of processes of social interactions across the international border and, b) the asymmetry of power. These two concepts have the analytical advantage of being able to apply from one end to the other of the continuum that goes from the micro to the macro levels of

analysis. That is, from the micro level of the social interaction between a migrant worker and his or her employer, to the macro level of the interaction between the national economies or governments or cultures, as long as they are relevant for the shaping of conditions for the international labor market where the undocumented migrant worker is inserted.

These basic concepts allow the analysis to follow different axes of the patterns of social interactions of the undocumented immigrant such as: a) the geographical location of actors or factors at each side of the border or; b) the structural location of actors or factors pertaining to the international labor market between the two countries or, c) the identification of the external processes of interaction characterizing either the demand side or the supply side of the respective country, within which there are interplays of internal labor market shaping conditions connected to those external processes of interaction as suggested in the diagram.

This definition of undocumented immigration from Mexico is not shared by the governments nor by the majority of the people of the two countries. The presence of undocumented immigrants from Mexico in the United States is predominantly viewed as an exogenous calamity. As a crime-related phenomenon thus, as a law enforcement problem which requires a police type of solution.

The same people doing the same thing are viewed in Mexico as people who go to theUnited States in search of a job to do things that American citizens are not interested in doing for a living. In a nutshell, Mexican undocumented migrants do something as legitimate as the benefits received by those who hire them in the United States.

The marked contrast between the perceptions or visions of undocumented Mexico-U.S. migration held respectively in the two countries concerned is not due to a lack of adequate information as much as it is due to a contrast between the respective national interests of these two countries, in turn associated with the asymmetry of power that characterizes relations between Mexico and the United States.

With the above definition we move to an empirical analysis of the two dimensions suggested above. This analysis results from different methodological approaches required by the difference explained above between the cultural and the interactional dimensions. Both pertain to the same phenomenon to the extent that values which shape perceptions leading to immigration policies belong to the immigration issue as much as the actual number of undocumented immigrants working in the agricultural production of a particular region of the United States. One dimension might not be directly related to the same facts than the other. Furthermore, one dimension could be in contradiction to the other or follow different dynamics. The theoretical assumptions followed in this analysis are, a) that the interplay between the two dimensions has to be understood before the undocumented

immigration phenomenon is under control and, b) that the same method of research can not be applied to the two dimensions.

There are in fact two "cultural" dimensions of this bilateral phenomenon. One corresponding to the conditions of the supply side in Mexico and another corresponding to the conditions of the demand in the United States. For the purpose of discussion of the theoretical frame of reference proposed in this paper, focus will be placed on the cultural dimension corresponding to the demand side of the international labor market, as it is shaped in the United States. For the "Verstehen" at the level of meaning of the "cultural" dimension of the undocumented immigration in the United States, an historical approach will be taken, led by the following hypothesis.

The public morality of those in the United States who believe that Mexican immigration is a threat or something exogenous and harmful includes an ideological construct that justifies in moral terms the sanctions or punishments levied against those identified or labeled as "illegal aliens." This ideological construct is a social construct in a similar sense in which Max Weber understood that element of the social relations to which he called the "Gemeinter Sinn."[14] as the intersubjective meaning commonly attached to a behavior or a symbol by the members of a community in a context of a social interaction.

What it makes the meaning attached to the presence of undocumented immigrants from Mexico stick in the social context of the United States is an act of power. Its exercise corresponds to an asymmetry of power between those who label[15] them "illegal aliens" and those who are so labeled. The common meaning of such a label is about some one (an alien) who has entered the United States braking the U.S. laws with the main purpose of doing something which will represent a cost or a burden to the American people.[16]

"Illegal aliens" are viewed today in the United States both, as a cause of some of the worst calamities that afflict the country, such as drug traffic, and as source of cheap labor. That is, both, as a problem and as a solution. The intensity of these views varies over time respectively. The contradiction between them however, becomes more acute in times of economic crisis.[17]

If we look at the history of migration from one country to the other, what stands out is the United States' interest in gaining access to cheap Mexican labor. The following quotation, drawn from the congressional hearings on migration held in 1926, is particularly eloquent:

> Mr. Chairman, here is the problem in a nutshell. Farming is not a profitable industry in this country, and, in order to make money out of this, you have to have cheap labor... in order to allow land owners now to make a profit on their farms, they want to get the cheapest labor they can find, and if they can get the Mexican labor it enables them to make a profit. That is the way it is along the border and I imagine that is the way it is anywhere else.[18]

For the purpose of the methodology suggested here, this quotation becomes even more significant when we learn that its author was John Nance Garner, who built his fortune on agricultural lands adjacent to Mexico, just north of Piedras Negras, Coahuila, and who became Vice-president of the United States a few years after making this statement in a congressional hearings.

A few years later we find the same clear "Gemeinter Sinn" of a national interest underlying the immigration policies of the United States. In 1953 Senator Walter McCarran declared the following before a Senate Committee:

> Senator [Elender], I think you will agree with me that on this side of the border there is a desire for these wetbacks... Last year when we had the Appropriations Bill up, the item that might have prevented them from coming over to some extent, was stricken from the Bill... we might as well face this thing realistically. The agricultural people, the farmer along the Mexican side of the border in California, in Arizona, in Texas... want this help. They want this farm labor. They just can not get along with out it.[19]

It is intriguing how these references to the cheapness of Mexican labor in congressional hearings testimony in the United States over several decades seem to assume that the Mexican labor force is a sort of a natural resource, something inexpensive by its very nature. What it is more relevant for the purpose of the theoretical framework used here, is the way this two statements reflect very eloquently the cultural understanding of Mexican immigrant labor among United States employers in a historical perspective. These statements allude to two levels of power asymmetry, one, between the U.S. employers and the migrant workers and; two, between the United States and Mexico. Here you have U.S. Senators talking about Mexican citizens as if there was no international law or as if Mexico did not exist as a sovereign nation to be dealt with about her own citizens. Here we have a power asymmetry reflected at both end levels; from the macro to the microdimensional. The latter reflected in the capacity of U.S. employers to exercise their power by imposing low wages upon the socially constructed vulnerability of the Mexican migrant. It suffices to compare the salaries compiled in the meticulous research conducted by Manuel Gamio. Gamio noted that the average salary paid to migrant workers in southeast Texas in 1926 was between $1.50 and $2.00 per day.[20] Twenty-four years later, Saunders and Leonard recorded average salaries in this same region at $2.50 an hour for a twelve-hour workday.[21] If we factor in inflation in the interim, we find that salaries have risen hardly at all in nearly 25 years, while the profit returns to agriculture in this region rose 1,000 percent in the same period, according to these same authors.[22]

Then followed the years of the Bracero Program, from 1942 to 1965. No one has described more knowledgeably or more eloquently the conditions of

extreme exploitation that migrant workers suffered during these years than Dr. Ernesto Galarza in his classic work, *Merchants of Labor: The Mexican Bracero Story*.[23]

During my years as a graduate student, when I posed as an undocumented migrant as part of an exercise in participant observation which I reported in my doctoral dissertation,[24] I had occasion to witness an event that reflected very eloquently the way in which the power asymmetry between Mexicans and U.S. citizens was brought into play to drive salaries down. It was the summer of 1969. I was in Weslaco, Texas, and had joined a group waiting on a street corner to be hired by a farmer. A truck drew up and stopped near the group. The driver gestured that we could climb aboard. About 20 of us did so, almost everyone who had been waiting. They took us to a ranch about 15 kilometers away. The driver of the truck got out, and we all got down. His first words to us were: "There's lots of you...." As if he had not expected us. Then he said: "Let's see... raise your hand if you want to work for a dollar an hour." Nearly everyone in the group raised his hand. "No... there are still too many of you," he said. Then he added: "Let's see, raise your hand if you want 75 cents an hour." The number of us who raised our hands dropped to half. As his voice rose in impatience he said: "No... there's still too many. Let's see, who wants the job for 50 cents an hour." The group of us raising our hands dropped to seven. Talking like someone who had repeated the same speech many times before, the foreman told those who had not raised their hands: "Ok, boys, you'll get a chance another time. Get on your way fast so I don't have to call the police and have you cited for trespassing."

As the big group of unhired workers moved away, they began to yell at us, clearly angered, as if in persisting at trying to get a job, even at low salaries, we had failed to show the hoped-for solidarity. Their mildest words for us were, "You hungry bastards." The foreman turned around toward the seven who had survived this "reverse auction," where those who won employment were those who offered the lowest price. The foreman gestured, and all the workers responded with a palms up gesture. I did the same as the others. When the foreman came around and saw my hands, he told me laconically: "Not you... you go with the others."

As I walked slowly toward the ranch gate I asked myself if this was the ultimate measure of power asymmetry between U.S. employers and Mexican workers, and how long it had taken to transform it into a shared code of communication, into a "Gemeinter Sinn," well understood and well accepted despite its clear disadvantage for the migrant workers. I asked myself at what point this disadvantage in hiring conditions had been transformed into an element in the culture of the labor market of migrants and their employers in a foreign country. Posterior reflection on this experience made clearer to me that this is some sort of a last degree of "freedom"

before reaching the point where work stops being a social relation between an employer and a "free" worker to become slave labor. Taking the theoretical perspective in which international labor migration is viewed as a social relation that takes place in the structural framework of an international labor market, this notion of a scale of "freedom" within which the worker acts in response to conditions that the employer sets, is relevant because it leads to the point where the worker's level of freedom disappears, and with it the nature of the social relationship. When this happens, as it does with slavery, we are no longer talking about a social relationship of labor but about a unilateral act of power.

Over more than 20 years of conducting research on undocumented migration,[25] I have seen very few improvements in the working conditions of the migrants. I thought I had seen everything until I visited the so-called spider holes that migrant workers are constructing today, at the end of the 20th Century, in the northern part of San Diego County. The migrants spend their nights in these holes. By day they work in the few crops that have not yet been edged out by changing land use patterns which convert agricultural land into the proliferation of residential developments that is taking over this area that formerly grew the most beautiful flowers in southern California, cultivated since the first plantings in the 1940s by Mexican hands.

To summarize: For decades, the United States has demonstrated an insatiable appetite for Mexican labor. This appetite is not constant. It has decreased in times of high unemployment, as during the economic crises of 1907, 1921, 1929-34, 1954, 1974, 1981 and 1992. Nevertheless, in none of these crises has the appetite for cheap labor fallen to zero. In the three most recent crises, I have been able to document a paradoxical situation: the crisis itself encourages some businessmen, who under normal conditions would not hire undocumented migrant workers, to turn to this labor force in order to lower their production costs as a way of dealing with the impacts of the crisis.

In all of these crises, measures have been proposed that would expel Mexican migrant workers en masse, offering ideological justifications that I will discuss in the following section. In many of these crises, there were broad expulsions of fully documented Mexican immigrants. Instances include the crises of 1907,[26] 1921,[27] 1929-34,[28] and 1954.[29]

What is important to note here in terms of the proposed hypothesis is, that the United States has demonstrated a long-standing and intense demand for Mexican migrant labor. But the United States wants to satisfy this demand for a resource which comes from abroad according to its own unilateral terms. In this way the United States is exercising the power asymmetry it holds over the country from which it extracts de facto the cheap labor force it seeks. Even when bilateral agreements have been signed that would regulate this demand, as was the case

with several of the *bracero* agreements, these were flagrantly violated, as documented by Craig,[30] Galarza,[31] Gamboa,[32] García,[33] Montejano,[34] Sobek,[35] and Taylor,[36] again testifying with each violation to the power asymmetry in U.S. relations with Mexico, even when the U.S. government has put its signature on a bilateral agreement with Mexico.

One could argue that the U.S. interest in Mexican labor has not been so much national as regional, although, as Gamboa has ascertained,[37] demand in the United States has geographic roots as far away as Washington State, on the border with Canada. What is clearly beyond question is that the U.S. government, when dealing with Mexico, has put all its might behind its interest in Mexican labor. The most recent expression of this government support is the United States' unilateral decision from the outset, to exclude labor migration from the agenda in the negotiations of NAFTA.

This degree of national support, by which the United States has historically guaranteed U.S. employers unrestricted access to Mexican labor, has led to a persisting official definition of undocumented immigration as a problem of criminality and law enforcement.

When public opinion reaches a high level of consensus around this official definition, it becomes equated with "national interest." At this level, the predominance of such a public definition makes politically impossible any alteration of the official position that equates "illegal aliens" with criminals, particularly because this definition has the function of producing savings to the U.S. economy. These savings are equal to the difference between the salary and benefits that an undocumented migrant receives as a function of being undocumented, and the salary that a U.S. citizen actually receives for the same work, particularly in regions and economic sectors where the hiring of undocumented workers is widespread. The implied equation for this function would lead to a result that could well total several billion dollars per year. This is equal to the costs the U.S. economy would be likely to incur in salary differentials if bilateral negotiations produced a legalization program that would regulate hiring practices, wages, working conditions, as well as the number of Mexican migrant workers which would correspond to the real size of a U.S. labor needs. When one imagines the economic, social and political meaning of such a notion of dealing with the undocumented immigrants from Mexico as a bilateral phenomenon related to a de facto international labor market, one can imagine the analogy of such changes with what implied in the 19th Century the rising cost of the black labor force in the United States once slavery was abolished. In this analogy lies one part of the explanation of why there is such a resistance from the part of the U.S. government to officially recognize the labor market nature and the bilateral causality that characterize and drive the phenomenon of undocumented Mexican migration. In

refusing to give this recognition, the United States is exercising an act of power which is essentially no different in nature than the act of power involved in justifying the enslavement of blacks in the 19th Century.

Although as yet little research has been done in this area, the profile of an hypothesis emerges from history. This is one which goes to the root of the problem addressed in this paper. That is, that the current and widespread economic interest in keeping the U.S. border with Mexico relatively open to the entry of undocumented migrants exists, not because there is a real need for labor or because the labor demand cannot be satisfied domestically, but because this is a strategy that can lower, or slow the rise of, salary levels in U.S. regions that draw Mexican migrants. In other words, the conditions of power asymmetry between these two countries make undocumented migrants vulnerable in terms of their human and worker rights in the United States. This allows U.S. employers to pay salaries and impose labor conditions that are inferior to those that would be acceptable to local workers. This decreases the salaries of undocumented migrants, but it also produces a wider impact on salaries since it drives down the salaries for other jobs that are near the bottom of the wage scale. In summary, this hypothesis could be stated as follows: undocumented migration from Mexico to the United States is maintained because it depresses wage levels, thus, the greater the oversupply of migrant labor, the most marked is the decrease in wage levels in the region. If this hypothesis can be confirmed, it would explain why the United States does not use its might to close the border to undocumented migrants, and why it took the decision not to include labor migration in the negotiations of NAFTA.

The attempt has been in the previous sections to reach a sociological Verstehen, "adequate at the level of meaning" of the "cultural" dimension of undocumented immigration in the United States. We turn now to the other dimension that it was called "interactional" where some basic socioeconomic characteristics of the undocumented immigrants from Mexico will be presented in a route toward an "Erklarendes Verstehen" of this phenomenon, for which methodological approach the concept of "circulatory migration" becomes crucial.

Circular Migration between Mexico and the United States

It is well known that many of the workers involved in immigration flows into the United States return to their country of origin. In the case of migration from Mexico to the United States, which has persisted for over a hundred years, not only has there been a return flow but it has included the majority of migrants. These workers return to Mexico after a migratory "career" that involves alternating stays in the receiving areas in the United States and in their home communities in Mexico.

Such a migratory "career" can continue for several years, but it generally ends with an aging worker's definitive return to Mexico. Obviously this is not true in every case. A growing proportion of migrants is choosing to remain permanently in the United States. Perhaps the decision to remain in the United States or to return definitively to the home community is a function of the intensity of the interaction between the sending community and the receiving community, reflected in the number of family members that the first-time migrant has in the United States. That is, the fewer family members a migrant has in the United States, the more likely it is that he will return definitively to Mexico.

Data obtained from the Zapata Canyon project support these hypotheses. They reveal a process of circular migration from Mexico to the United States which is clearly related to the geographical proximity of these two countries. By circular migration it is understood here, the process by which an individual alternates stays in Mexico and the United States, for more than six months, between his or her family residence and job residence, until either age, success or failure, makes him or her to permanently establish his family residence at some point of his or her circulatory route, either in Mexico or in the United States.

The notion of circular migration holds methodological and theoretical implications. Methodological, because of at least two reasons, a) length of stays in the United States might be increasingly long, returns to Mexico become increasingly short and job residence becomes permanent as a result of family reunification. Then, new entries to the United States from Mexico might increase the volume of the migratory flow giving the observer the impression of an increase in immigration to the United States, when in fact he or she is observing an increase in the intensity of a circulatory movement, including Mexican citizens who might have moved on a permanent basis to the United States. On the other hand, b) when measured properly, circulatory migration might become an indicator of the intensity of the interactions between "structural conditions" and "factors" located at the two sides of the border, which are associated to the phenomenon of international migration between the two countries.

The notion of circular migration holds theoretical implications because the definition of a migrant should no longer depend on his or her position on the map but on his or her engagement in an international labor market. Traditional definitions of a migrant require his or her crossing of a geographical boundary for certain period of time. The notion of a circulatory migration should be operationalized from the theoretical assumption that a migrant is a person who is no longer a permanent resident of his or her home town because of a decision that implies joining an international labor market by responding to a perceived labor demand in another country. This means that a migrant is a migrant from the moment he or she has left home with the intention of looking for a job in another country.

For the purpose of estimating of the number of international migrants, the count should begin when they join the migratory circle, regardless of whether that person has crossed an international border or not. The migratory circle includes the geographical space between the last permanent residence and the place of migratory destination. The latter could be of various types—from an attempted destination to an actually reached one. The analyst's selection of the type of migratory destination might depend on the scope of the analysis. The important implication here is to include all persons who are in the international migratory circle in the enumeration of international migrants, whether or not they have left the country of origin or reached the country of destination.

There is need is for the concept of "circulatory migration" because to know the actual cost and benefit of international migration for the countries of origin and destination respectively one needs to know how many there are in the "migratory circle." The operationalization of this concept should allow a better understanding of the relationships between the costs and benefits of international migration for the two countries by taking into account where and how the costs are borne for the reproduction of the migrant labor force. In other words, in the theoretical context of international circular migration, one could say: a) that circularity exists between an economy of origin and an economy of destination which are brought into interaction through migration; b) if the migrant is understood as "human capital"[38] needing to be reproduced, the reproduction of this "capital" involves a cost to the economy of origin and a net benefit for the economy of destiny, where this human capital is generating wealth with its labor; therefore c) the economy of origin is subsidizing the economy of destiny where this subsidy is equal to the savings that the receiving economy realizes when it takes advantage of human capital for which it did not pay the costs of reproduction.

Both the methodological and the theoretical implications of the concept of circulatory migration should be analytically viewed from a Weberian perspective as an "ideal type"[39] of an international labor market. This is to say, a social and economic construct. The social sense, in its microdimensional level derives from the nature of a social relation between its most significant actors, namely the U.S. employer and the Mexican migrant. In its macrodimensional level it involves the social, political, economic and cultural relations between Mexico and the U.S. as nations.

The operationalization of the concept of "human capital" corresponds to the operationalization of the concept of "structural conditions" as one of the "factors" both, on the supply side, in terms of its production and, on the demand side, in terms of its use. It is hoped that this conceptual framework will suggest the means to measure the dimension of costs and benefits of international migration, something not attempted to date, perhaps because no adequate theoretical framework existed.

Migratory Flows

The circular nature of international migration between Mexico and the United States can best be measured when we are able to identify migratory flows in spatial, temporal and numerical terms. The fact that most undocumented migrants cross at some point along Mexico's northern border, where they can be interviewed, has enabled the Zapata Canyon Project to identify principal flows in terms of their origin and destination. The measurement of migration flows has been the surest means devised thus far for calculating variations in the volume of undocumented migration; this is the case because efforts to measure undocumented migrant stocks are hindered by the fact that the undocumented status of these individuals forces them into a covert existence in the United States. Measurements of migration flows are even more valuable when we can determine the socioeconomic characteristics of the migrants, even though this technique has not allowed us to determine the number of undocumented immigrants there are in the United States. The ongoing research of the Zapata Canyon Project has illustrated the importance of focusing on flows as the key element in the analysis of international migration between Mexico and the United States.

The following maps depict empirical findings of two independent research projects. One is the above mentioned Zapata Canyon Project. The other corresponds to the Survey on Migration in the Northern Border of Mexico which acronym in Spanish is EMIF.[40] In contrast to the Zapata Canyon Project, EMIF measures migratory flows from south to north and from north to south. Its methodology derives from the theoretical concept of "circulating migration." It is based on an adaptation of what biology statisticians call "sampling of mobile populations." This sampling technique is used for the estimate of numbers of migratory species. From whales to dolphins to salmon or migratory birds or blood cells. As it is the case with some migratory species, the circular nature of the migratory phenomenon between countries, in a theoretical frame, involves dimensions of time and space. The conceptualization of these dimensions allowed for the operationalization necessary for the design of the sample of continuous migratory flows. These were developed and administered by a team of scientists of El Colegio de la Frontera Norte, headed by the author, by means of the EMIF. The empirical definition of "space" through which "migratory circulation" occurs, is associated with the concept of "migratory routes." These are like rivers that flow with two-way currents, connecting places of origin with places of destination of a circulating migration.

In the case of the observation of migratory flows, after the route of these virtual rivers has been empirically established , we define the place of empirical observation for the smallest unit of sample space, as if resorting to the narrowest part of the river in order to better view what passes through the current. To this end, we find

the narrow sections of these "rivers" in bus stations, airports, railroad stations, and customs and immigration inspection places along the freeways.

All of these points are identified as corresponding to all the points of entry to Mexico, from or to the United States, which represent levels susceptible to conforming even more when "doors" or other units of space that are smaller, are systematically identified in airports or bus stations through which displacements occur through the "migratory rivers." Once that, say, a bus station is identified as the narrowest sampling unit, we complete a systematic count of all the persons who pass through this "door" in units of time. Periods of three months are the most amount of time used. During this time, we make a complete census of people who cross. This occurs with the end of taking sample units of the smallest amounts of time which are then selected at random in accordance with conventional sampling techniques for designs of multistage samples.

Maps 1 to 6 indicate with arrows the set of Mexican states which consist of the place of origin of migrants, both documented and undocumented, who were found to have the place of destination indicated with the arrow in the map. The arrow starts in the Mexican state with the largest number of migrants in terms of their state of origin. Data used for the maps compiles the whole region defined by the shadowed area in the map. Arrows point at the state of destination of the migratory flow in the United States.

The estimated number of migrants is based on conventional sampling procedures applied to the sample frame of the "mobile populations" following the same principles used by biology statisticians for their sampling technique mentioned above.

Maps 7 to 12, are based on the Zapata Canyon Project's data. The reference to the number of cases corresponds to actual individuals who were personally interviewed based on the questionnaire that has been administered three days per week, ever since September of 1987 to the present.

Maps 13 and 14 indicate flows of returned migration from the United States to Mexico. In accordance to the notion of "circulating migration," "returned migration" does not necessarily mean a return for good. Numbers of this flow indicated in the map correspond to individuals who, in the period during which the survey was conducted, were found to be returning to Mexico after being identified as migrants, coming from the United States. Data shown in the maps correspond to the first time ever that the actual flows of returned migration is estimated directly from a systematic random sample of actual migrants.

Map 1

This map shows the state of Guanajuato as the place of origin of the highest number of migrants, who were found to come from the region defined by the shadowed area, on their way to the U.S. southwest region, with the state of

California as the place of destination for the highest number of migrants coming from the shadowed area in the map. This area represents historically the place of origin of the oldest and largest source of out labor migration from Mexico to the United States. This was the targeted region for the first recruiting efforts by U.S. Congress-funded recruitment programs during the second decade of this century.

Map 1. Destination in the United States of the Flow of Migrants Whose Stated Permanent Residence Is in One of the Following States: Guanajuato, Michoacán, Jalisco, Zacatecas and San Luis Potosí

Map 2

This map shows the origin and destination of U.S.-Mexico border migrants. The arrow indicates the highest numbers corresponding to this short distance flow as it originates in the state of Coahuila and as it ends in the state of Texas. Data from this and other COLEF surveys indicate a northward tendency in the place of origin of the majority of migrants. This is to suggest that there seems to be a tendency to shorten the distance between place of origin and place of destination of the international migratory phenomenon under study.

Map 4. Destination in the United States of the Flow of Migrants Whose Stated Permanent Residence Is in One of the Following States: Oaxaca, Guerrero and Morelos

among the majority of the labor migrants going to the United States. The ethnic group in the majority of migrants coming from the states of Oaxaca and Guerrero are the Mixtecos. They are atypical migrants in more than one sense because they tend to fund their respective cost of migration in U.S. dollars. This is to suggest a factor of solidarity of migrants already in the United States whose savings are the main source of funding for the migration of others from the same ethnic group. The majority of the rest of migrants tend to finance their journey to the United States with Mexican pesos, meaning the migrant's own resources. As in the majority of Mexican migrant's place of destination, the state of California appears as a virtual mecca for Mexican migrant laborers. Both the Zapata Canyon and the EMIF projects show the state of origin of more than 50% of the Mexican migrants both documented and undocumented, with the metropolitan area of Los Angeles as the place of destination of 75% of the total found in the state of California.

Map 5

This map depicts the flow from Central Mexico with the Federal District (Mexico City) as the place of origin of the highest number of migrant workers going to the United States with the predominance indicated by the arrow and the shadowed area. Migrants from Mexico City, both documented and undocumented, are newcomers in the statistics of out migration from Mexico to the United States. They appeared within the 10 states with the largest numbers of international migrants, only 15 years ago. Today, they seem to compete for the first place as a place of origin of undocumented migration from Mexico. This is particularly the case of the flow that passes through the city of Tijuana.

Map 6

This map shows the region of origin of the lowest proportion within the totals of migrant workers from Mexico to the United States, with the state of Veracruz as the place of origin of the highest numbers and the state of Chiapas with close to nil migration to the United States. As the arrow in this map suggests, these migrants tend to cross the border at the closest distance to the United States.

Maps 7 to 12

These maps represent accumulated figures corresponding to an eight-year period, as opposed to the EMIF's data, which correspond only to the twelve-month period between 1993 and 1994. These differences in the time span of these two sources of data are the main reason for the differences in the direction of the migratory flow depicted in the respective series of maps. Another important difference is the

sample base. Zapata Canyon Project's data correspond to actual number of cases with no statistical bases for a stochastic generalization of the universe of undocumented immigrants. In contrast, the maps based on EMIF's data, complies with all the assumptions required for the statistical estimates indicated in the respective maps.

of regional distinctions becomes more apparent in the empirical estimation of the migratory flows. Map 13 shows the western states of the two countries connected by migratory flows. Map 14 shows a similar connection between the state of Texas and the eastern and northern central regions of Mexico.

The circulant process of migration suggested in this paper does not mean that the migratory flows indicated in the maps presented here necessarily correspond to different individuals with different socioeconomic characteristics. Actually, one

individual could appear in different flows within a short period of time. The importance of the empirical notion of migratory flows has to do with differences in the conditions of U.S. labor demands in interaction with conditions of Mexican labor supply. We have found that it is the changing conditions of the international labor market studied here where the notion of migratory flows make a difference. This is to suggest that joining the migratory flow to California might represent a different outcome than joining the migratory flow to Texas for a Mexican migrant worker either documented or undocumented.

International Migration as a Process of Interaction Recent Findings From The Zapata Canyon Project[41]

Some interesting data sources have been drawn regarding basic socioeconomic characteristics of undocumented immigrants from Mexico over the last 6 years. In regard to gender, there is a relative stability in the proportion of women. It should be noted however, that there are significant variations when data is broken down by state of origin. Then, migrants from the metropolitan area of Mexico City show the highest proportion of women (24%) whereas in states more rural in the origin of migrants such as Guerrero that proportion drops to less than 10 percent. An important methodological finding could be stated. The more urban in origin, male and female migrants' data should be analyzed separately in order to account for significant differences by gender in migratory behavior.

In regard to age, data from the Zapata Canyon Project suggest there is a tendency toward a higher concentration in the most productive age cohorts (between 20 and 30). This could indicate an increasing competition in the labor market in the United States and/or a shorter "migratory career," meaning the time through which an individual keeps himself or herself in the circulatory process of migration between the two countries.

In regard to education (years of school attended), it is interesting to note a decrease in the percentages of the least educated, which suggests an increase in the "human capital" value of the undocumented immigrants.

One of the most important findings of the Zapata Canyon Project is the relatively rapid increase of the urban origin of undocumented immigrants from Mexico (13% in less than 6 years). A hypothesis could be drawn from this finding in the sense that there is a higher cost for the economies of origin of these migrants associated to an outmigration of a labor force that appears to be of an increasingly higher "human capital" value.

Data resulting from the question, "Have you ever had a job in the United States?" provide some empirical foundation to the notion of a "circulatory migration" put forward here. The increasing pattern of the affirmative responses

suggest an increasingly intensive circulatory movement of these migrants between the two countries.

Data from the Zapata Canyon Project show some patterns of destination choice among undocumented immigrants from Mexico. They confirm previous findings about the increasing preference for California in general and Los Angeles in particular, among undocumented immigrants from Mexico. The high degree of concentrated migrant flow through the city of Tijuana is congruent with the preference for California. Almost two-thirds of the total number of Mexican undocumented immigrants in route to the whole United States is heading toward California. This pattern of concentration seems to be enhanced by the relative decline in the preference for other regions of the United States or Canada in addition to the decline in the percentages of migrants who responded not to know where they were heading at the time when they were interviewed.

Finally, data from the Zapata Canyon Project yield empirical support for contentions made above about of the persistence of a United States labor demand for Mexican undocumented immigrants. There is an increase in the reported previous job experience in the United States of individuals getting ready to enter the United States again, except in farm working where a clear decline seems to be taking place. This seems to be congruent with the patterns of increase in education levels among undocumented immigrants.

Toward a Pragmatic Approach to Manage Labor Migration from Mexico

In a manner of a symbolic synthesis of the two parts discussed above, an idea for the initiation of a bilateral process of rationalization of the labor migration phenomenon between the two countries is advanced here.

In early 1992 there was an important meeting in Washington, D.C., at which representatives of the Mexican and U.S. federal governments discussed the problems of violence on their common border. On the eve of that meeting, a high-level functionary in the U.S. federal government, who asked not to be identified, told me, “there are no official proposals from the Mexican side on what to do about undocumented immigration; they only have proposals to talk about the problem, but not about how to resolve it.” Meanwhile, of course, it is painfully clear that the U.S. government does have proposals. These proposals all share a common characteristic: all adopt the law enforcement focus that the U.S. government consistently places on undocumented migration. The U.S. government never wavers from defining this phenomenon as a crime problem requiring police-type solutions. The persistence of this view of migration from Mexico has led the U.S. government to categorically reject on principal the idea of considering labor migration within

the negotiations of NAFTA. The U.S. government will only agree to deal bilaterally with the problem of undocumented migration if it is in relation to law enforcement policies. Its refusal to view the issue as a labor issue has been inflexible. However, this inflexibility has not been expressed openly and hence it has not appeared in the mass media. In my view, it is a political miscalculation on the part of the Mexican government to allow the U.S. government to acknowledge its inflexibility only within internal diplomatic circles. I had the opportunity to attend an ANUIES-PROFMEX conference in Mazatlán in 1990, to hear the opening of the free trade negotiations.

A high-level functionary from the office of Ambassador Carla Hills presented the United States' official position on refusing to include the migration issue as part of the negotiations of this accord. The rationale put forward since that time is that labor migration would only be included in the negotiation of a "common market," not of a "free trade agreement." This rationale masks the fact that the United States prefers to continue addressing the migration issue unilaterally as a crime issue, since undocumented migration provides an inexhaustible source of cheap labor that the United States can regulate and has regulated according to its economic needs. It also has an additional advantage: these migrants serve politically as scapegoats every time the U.S. government wants to hide from the U.S. public the true causes of some hardship such as high rates of unemployment, drug trafficking, or social unrest such as the recent disturbances in Los Angeles. To address the migration issue as a labor phenomenon would mean bringing it to the bilateral negotiating table, and that, in turn, would increase the costs of this labor force that is kept cheap by virtue of the fact that it is kept undocumented, and hence criminal. The United States' refusal to focus on undocumented migration as a labor issue saves the U.S. economy several billions of dollars every year. This is the chief reason for the current U.S. position, and it is what lies behind U.S. inflexibility on dealing with the migration issue as anything other than a law enforcement issue.

This inflexibility is nothing other than a flagrant expression of the power asymmetry characterizing the U.S.-Mexico relationship across all dimensions, from the macro to the micro. In this light, the United States is unjustified in saying that "there are no official proposals from the Mexican side." This is asking to blame the victim.

This situation suggests that the Mexican government should formulate a proposal detailing what has been voiced by a series of Mexican presidents, government ministers, and high-ranking members of Congress: a) that Mexico wants to export products, not people; b) that undocumented migration is a labor issue and a human rights issue; c) that these issues should be negotiated bilaterally in depth and over the long term. This has been the position of the Mexican government during the

last four administrations, ever since President Echeverría decided over 20 years ago not to seek renewal of the Bracero Program agreements which had lapsed in 1965. The U.S. government has never officially accepted points b) and c) since the U.S. view does not accept that migration is a trans-border issue demanding "international cooperation." It continues to hold that migration is a domestic national security issue or a law enforcement issue. In order to correct this lack of a precise definition of Mexico's national interests in the issue of undocumented workers, I propose a strategy that includes the following steps:

Step A is agreement by the two national governments to form a Bilateral Commission with three objectives:

A1) to produce a bilateral report that defines and describes legal and undocumented migration, both of Mexican citizens to the United States and U.S. citizens to Mexico;

A2) to discuss and defend this report before representatives of the respective legislatures and before representatives of the major media networks, of key associations from the private sector, and of organized labor from each country;

A3) to act as consultants to the official negotiators of a Migration Treaty between the two countries, with commission members filling this role in their respective countries.

Negotiating such a treaty would be step B, which could only be attempted once the set of objectives outlined above—A1, A2, and A3—had been accomplished.

The irrationality that permeates the mythology of Mexico-U.S. migration leads us to assume that a necessary precondition for reaching agreement on a Labor Migration Treaty would be to de-mythify undocumented immigration. This could be accomplished through a scientific analysis that would be produced and supported bilaterally, making it acceptable and credible on both sides of the border. Under current conditions, it is impossible to reach any agreement that would be acceptable to the respective political institutions and civil societies of Mexico and the United States. It is imperative that these conditions change. This would be the primary objective of the proposed Bilateral Commission. This commission would be made up of one member from each country's respective government sector, and two members each per country from the business sector, organized labor, and academic institutions. It would have a budget with which to finance independent studies on the condition that they be bilaterally directed. Its secretariat or permanent staff would include members from both countries; these individuals would be charged with implementing the decisions of the commission. Once the research efforts had produced their results and the negotiations of the Migration Treaty had begun,

commission members would act as consultants to their respective country's team of negotiators, except in the case of government representatives on the commission, who could serve as members of their country's negotiating team. The complexity of the issue of migration between these two countries is so great that we should not expected its negotiation to be any less intricate than the negotiation of NAFTA. What the United States has to gain from a Labor Migration Agreement is not of a different nature than what is expected to be gained with NAFTA; namely, a neighboring country economically capable to buy more U.S.A.- made products and politically stable to institutionalize similar rules of the game than those of the neighbors to the north, joining strategies on a regional basis in order to compete successfully with the European Community and the Asian countries.

Notes

1. This is the Zapata Canyon Project which basically consists of a survey technique where personal interviews are systematically conducted at the main crossings sites of the Mexican-U.S. border in the cities of Tijuana, Mexicali, Ciudad Juarez, Nuevo Laredo and Matamoros, to a randomly selected sample of individuals on the Fridays, Saturdays and Sundays of every week, ever since September of 1987 to the present. This project has produced the only time series data base on the flows of undocumented migration from Mexico, other than the statistics on apprehensions produced by the U.S. Immigration and Naturalization Service. Previous findings from this project have been reported, among others, in the following publications by the author of this paper: "Undocumented Immigration: Research Findings and Policy Options," in R. Roett, *Mexico and the United States: Managing the Relation*, Boulder, Co.: Westview Press. 1988; "Measuring the Flow of Undocumented Immigrants," in W. Cornelius and J. A. Bustamante eds., *Mexican Migration to the United States: Origins, Consequences and Policy Options*, San Diego-La Jolla, CA: Center for U.S.-Mexico Studies-University of California. 1989; "Undocumented Migration to the United States: Preliminary Findings of the Zapata Canyon Project," in: F. Bean et al. eds., *Undocumented Migration to the United States*, Washington, D.C.: The Rand Corporation and the Urban Institute Press. 1990.

2. Max Weber, *Grundriss der Sozialokonomic*; III Abteilung, *Wirtschaft und Gesellschaft*, Tubingen: Verlag von J. C. B. Mohr (Paul Siebeck). 1925. In the first section entitled "Methodische Grundlagen" (Basic Methodological Premises), section 5, pp. 3-4, Weber makes a dual distinction between two kinds of "understandings," after his famous dictum that "Verstehen" is what sociology is all about. This dual distinction is between a)"aktuelle Verstehen," which refers to the understanding of culturally meaningful behavior directly observable and, b)"erklarendes Verstehen," which refers to the understanding that is reached for explanatory purposes, through the cultural interpretation of social actions. This dichotomy inspired the basic distinction made in this paper where the "cultural dimension" corresponds to an attempt toward b and the interactional dimension corresponds to an attempt toward a.

3. J. A. Bustamante, "Structural and Ideological Conditions of the Undocumented Immigration to the United states." *American Behavioral Scientist*, Vol. 19, No. 3. New York, N.Y.: 1976; "Commodity Migrants: Structural Analysis of Mexican Immigration," in : S. R.

Ross ed., *Views Across the Border: The United States and Mexico*. Albuquerque, N.M.: University of New Mexico Press. 1978; "Mexican Migration; Political Dynamics of Perceptions" in: C. Reynolds and C. Tello eds. Stanford, Ca.: University of Stanford Press. 1983; "Interdependence, Undocumented Migration and National Security" in: Jorge A. Bustamante et al. eds. *Labor Market Interdependence*. Stanford, Ca.: University of Stanford Press. 1992.

4. Documentation in support of this assertion appears in, J. A. Bustamante, "El debate sobre la 'invasion silenciosa'," *Foro Internacional*, Vol. 17, No. 3, El Colegio de México. México, D.F. 1977. pp. 403-417.

5. See note 2.

6. See note 2

7. Such as an individual who is actually crossing the U.S.-Mexico border at a place where there is no inspection by the U.S. authorities. Individual whose behavior can be empirically accounted for in terms of socioeconomic characteristics and statistical categories.

8. Here, the specific reference corresponds to Weber's discussion of this concept in sections 6, 7 and 8 of the first chapter of *Wirtschaft und Gesellschaft*.

9. It is argued here that one of the most serious distortions of Max Weber epistemological approach to the study of social relations comes from Talcott Parsons' translation of "Sinnhaft adaquat" and "Gemeinter Sinn" as "subjectively adequate" and "subjective meaning" respectively. There are few concepts as crucial for the understanding of Weber's sociological theory as the concept of "Sinn" (meaning). My reading of the original writings leads me to interpret this concept as "a cultural sense that is commonly attached to a behavior or a symbol which meaning is intersubjectively shared by the members of a community." That is an interpretation of "Sinn" as a social construct, distinctively independent in origin from the subjective individuality. Parsons' rendition of "Sinn" results closer to his own epistemological approach to the social action which is anchored in the subjective individuality of attitudes. Weber's explicit preoccupation for a legitimate identity of sociology as a field of knowledge, places the datum of "Sinn" in the social nature of the community, whereas Parsons places the datum of "subjective meaning" in the psychological nature of the individual.

10. The second paragraph of section 7 of the first chapter of *Wirtschaft und Gesellschaft*, leaves no doubt of Weber's emphasis on the *overt* behavior as a datum required for the "Kausal adequat" level of scientific understanding of social actions, which is to be understood in contrast to the *cultural* nature of the datum required for the "Sinnhaft adequate" level.

11. This methodological distinction does not mean that cultural elements cannot be counted or that they are not susceptible of statistical analysis. The difference is one of epistemological nature. It has to do more with a still weak scientific development of social sciences where no analytical instruments have been developed yet to grasp and render directly measurable some intersubjective elements of culture, than with a positivistic distinction between "hard" and "soft" data.

12. Wolfang J. Mommsen, *Max Weber und die deutsche Politik 1890-1920*, pp. 23-54, quoted by Dirk Käsler in *Max Weber: An Introduction to His Life and Work* (Chicago: University of Chicago Press, 1988). In this quote Mommsen refers to the detailed studies that Weber made of agriculture in the region of the Elbe River, in which he analyzed in over 12 publications appearing between 1892 and 1894 (still untranslated from the German) the conditions of the agricultural workers, including Polish migrant workers. Many of Weber's ideas that are particularly relevant to labor sociologists appear in this series of

works, commissioned by the Verein fur Sozialpolitik in 1890 to be conducted by Weber, along with Thiel, Conrad, and Sering. My understanding of this part of social and economic theory where Weber most thoroughly develops his sociological notion of a labor market came from a reading of the book by Dirk Käsler, cited above, and Wolfang J. Mommsen's later work, *The Political and Social Theory of Max Weber* (Chicago: University of Chicago Press, 1989).

13. For a thorough analysis of the treatment that Weber gives to the topic of power asymmetry in certain labor relations, see chapter 3, on agricultural workers, in Dirk Käsler's book on Weber, cited in the previous footnote.

14. See note 8. The understanding of this concept was not enhanced by the translation into Spanish done in Mexico by a team headed by José Medina Echavarría at El Colegio de México, first published in 1944, which rendered "Gemeinter Sinn" as "sentido mentado." In a work by the author entitled "The Parsonization of Weber in American Sociology," presented at the annual congress of the American Sociological Association held in Washington, D.C., in 1970, I propose that this concept should be understood as "the cultural sense that a community attach to a behavior or a symbol" which is used or expressed in the interactional process of constructing a social relationship. Only thus is the concept compatible with the epistemological principle on which Weber based his insistence in differentiating psychology from sociology; that is, "Gemeinter Sinn" is not located in, nor does it stem from, the individual psyche but rather from the social surroundings where we find the social constructions that shape the culture of a community.

15. This concept should be understood as used in "labeling theory." See: Bustamante Jorge A., "The Wetback as Deviant, An Application of Labeling Theory," *American Journal of Sociology*, Vol. 7, No.4. University of Chicago. Chicago, Ill.: U. of Chicago Press. 1972. Pp. 706-718.

16. Both the intensity and the extension of the labeling in the way used here, becomes exacerbated in periods of economic recession in the United States when "illegal aliens" become the scape goats of the calamities that afflict American communities, such as unemployment tax burdens, government budget deficit, health problems (from AID's to TV), air pollution in the city of Los Angeles etc., as it has been documented in: Bustamante, J. A. "The Mexicans are Coming: From Ideology to Labor Relations," International Migration Review Vol. XVII, No.2 (summer) 1992.

17. This contradiction appears documented in, Bustamante J. A., "The Mexicans are Coming: From Ideology to Labor Relations," cited in footnote 12. A more current evidence of this contradiction can be found in the contrast between the verses distributed in May of 1993 by Mr. William J. Knight, Assemblyman representing the 36th California district and former mayor of the City of Palmdale, and the table that appear in the following page, showing the persistence of undocumented immigrant labor demands in the last 6 years in spite of the economic recession in the United States.

18. U.S. Congress, Hearings before the Committee on Immigration and Naturalization, 1926. Washington, D.C.: U.S. Government Printing Office. 1926. Pp. 20-24

19. U.S. Senate. Subcommittee of the Senate Committee on the Judiciary, S.1917. Appropriations Hearings. 1953. P. 123 (Senator McCarran).

20. Manuel Gamio, Mexican Immigration to the United States. New York: Dover Publications, 1971.

21. Lyle Saunders and Olen F. Leonard, *The Wetback in the Lower Rio Grande Valley of Texas*. Inter-American Occasional Papers, No. 7 Austin: University of Texas Press, 1951, pp. 16-17.

22. Ibid., p . 18.

23. Here are the final paragraphs of Galarza's book, which support the first hypothesis presented in this paper:

"The picture of the ideal worker drawn by the managers of migration for trade-unionists to contemplate, was that of the man of the barracks, the main in a camp who spent all of his time under supervision if not under surveillance. Occasionally some of these total communities were surrounded by barbed wire, though this was in any event only symbolic. Though invisible, a more effective barrier surrounded them—the social distance created by differences in language, customs and unfamiliar patterns of character and behavior. Outside the barracks the limits of freedom were prescribed, and they were also the limits of the job. Liberty had found its economic determinant.

"No doubt efficiency lay in this direction and not in that of the man of the family; of the spontaneous relationships of the free life after work; of the street corner, back yard and meeting hall talk to discover interests commonly held and perhaps to devise ways in common to protect them, to discover the vital connections between work and citizenship."

The image of the perfect farm laborer that was thus in the making under administered migration was not, unfortunately, one that could be seen only at home. Each time that California's industrial farmers drew heavily on some alien reservoir of cheap labor they called it to the attention of foreign lands.

"It could hardly be avoided. Commercial agriculture, bidding in a world stirred by agrarian revolt, invited inspection. What it had to show, behind its dazzling efficiency, was the managed, not the autonomous, man.

"The trumpet calls of the New Frontier were still echoing when Senator Harrison A. Williams, Jr., chairman of the Senate subcommittee on migratory labor, posed the question: "If a man in an underdeveloped country can point to our migratory farm workers and ask why we have not set our house in order, what answer shall we give him?"

"The answer seemed to come in the words of four patricians of industrial agriculture testifying at a congressional hearing, the Messis. William H. Tolbert, Bruce Sanbom, Jr., George Lyons and Leland J. Yost: 'The same thing was true even in the Roman Empire. When they reached a stage of civilization they had to reach out to other areas where there was a lesser standard of living to bring in those people to do the menial tasks.'

24. Jorge A. Bustamante, "Mexican inmigration to the United States; the Social Relations of Capitalism," Ph.D. dissertation. Department of Sociology and Anthropology, University of Notre Dame. January 10, 1975.

25. I refer to the following works where I developed ana analytical distinction between the economic or "structural" dimension and the ideological or political dimension of undocumented immigration from Mexico to the United States: J. A. Bustamante, "Commodity migrants: Structural Analysis of Mexican Immigration," in: *Views Across the Border: The United States and Mexico,* Stanley Ross (ed.). University of New Mexico Press. 1978. Pp. 183-203; J. A. B. "Condiciones estructurales e ideológicas de la emigración mexicana indocumentada a los Estados Unidos," in: *El Economista Mexicano,* Vol. 12, No. 2, March-April, 1979. Pp. 24-38; J. A. B. "La migración indocumentada México-Estados Unidos:

Relación entre dinámica política y estructuras económicas," in: *Primer encuentro sobre impactos regionales de las relaciones económicas México-Estados Unidos*, vol. 3, Eliseo Mendoza Berrueto (ed.) 1992. Pp. 241-310; J. A. B. "Mexican Migration: Political Dynamics of Perceptions" in: *United States-Mexico Relations: Economic and Social Aspects*, C. Reynolds and C. Tello (eds.) Stanford University Press. 1983. Pp. 259-276; J. A. B. "La migración de los indocumentados," in: *El Cotidiano*, (special issue 1) 1987. Pp. 13-29; J. A. B. "La política de inmigración de Estados Unidos; Un análisis de sus contradicciones," in: *Migracion en el Occidente de México*, El Colegio de Michoacán. 1988. Pp. 19-40.

26. We learn of these conditions through the criticisms and denunciations that writers from the Liberal Party were able to publish in opposition newspapers during the era of Porfirio Díaz. The following paragraph is an eloquent example. It is drawn from one of these publications, "El Colmillo Ilustrado," and was published on March 8, 1905.

"On previous occasions we have referred to the mistreatment suffered by Mexicans who migrate to the United States. The representatives of our government in that country are not in the least concerned about this suffering which is so evident among our fellow countrymen who are in that Republic. Because of their lack of interest, we find that many of our compatriots are wandering, unable to find work, half naked, and dying of hunger. The government of Mexico is to blame when Mexicans abroad are made victims of mistreatment and abuse. This blame accrues because of their lack of vigor in defending these people's rights. Our government must insist that the fundamental rights of our citizens in the United States be respected. The dignity of our nation demands it" (p. 30).

27. See J. A. Bustamante, "El debate sobre la `invasión silenciosa'. *Foro Internacional*, vol. 17, no. 3 (El Colegio de México), 1977. Pp. 403-417.

28. The two best works on the expulsions of Mexicans during the years of the Great Depression are by Mercedes Carreras de Velazco, *Los Mexicanos que devolvió la crisis 1929-1932* (Dirección General de Archivo, México, D.F.: Secretaría de Relaciones Exteriores), and, by Abraham Hoffman, *Unwanted Mexican-Americans in the Great Depression: Repatriation Pressures, 1929-1939* (Tucson: University of Arizona Press, 1974).

29. See Juan Ramón García, *Operation Wetback: The Mass Deportation of Mexican Undocumented Workers in 1954* (Westport: Greenwood Press, 1980); and, Julián Samora, *Los mojados: The Wetback Story* (Notre Dame, Ind.: University of Notre Dame Press, 1971).

30. Richard B. Craig, *The Bracero Program: Interest Groups and Foreign Policy* (Austin: University of Texas Press, 1971).

31. Op. cit.

32. Erasmo Gamboa, *Mexican Labor and World War II: Braceros in the Pacific Northwest, 1943-1947* (Austin: University of Texas Press, 1990).

33. Op. cit.

34. David Montejano, *Anglos and Mexicans in the Making of Texas, 1836-1986* (Austin: University of Texas Press, 1990).

35. María Herrera Sobek, *The Bracero Experience: Elitelore versus Folklore* (Berkeley: University of California Press, 1979).

36. If we had to rely on the research of a single author to prove our first hypothesis, the research conducted by this conscientious scholar from the 1920s through the 1980s would suffice. See Paul S. Taylor, *Labor on the Land: Collected Writings, 1930-1970* (New York: Arno Press, 1981).

37. Op. cit.

38. This concept is used as understood by G. S. Becker in *Human Capital; a Theoretical and Empirical Analysis*. New York, N.Y.: National Bureau of Economic Research. 1975.

39. At least three sources should be consulted for a basic understanding of what Weber meant by an "ideal type": M. Weber, an "ideal type": *Economy and Society*, (edited by Guenther Roth and Claus Wittich) New York, N.Y.: 1968. Pp. 20-22; M. Weber, "The Meaning of Discipline," in: *From Max Weber* (H. H. Gerth and C. Wright Mills (eds.) New York, N.Y.: Oxford University Press. 1958. P. 42 and; M. Weber, "Objectivity in Social Science and Social Policy" in: *The Methodology of Social Sciences*, E. A. Shils and H. A. Finch (eds.). New York, N.Y.: Free Press. 1949. P. 104.

40. This research project was originally submitted to a competition for research projects to be funded by the World Bank and under the conditions of competition established by the World Bank, organized by Mexico's Secretary of Labor and the National Council of Population. The maps are drawn from data corresponding to the first year of this survey 1993-94.

41. For a description of this project see note 1.

Contents

Volume 1 • Thematic Chapters

The Quantification of Migration between Mexico and the United States
Frank D. Bean, Rodolfo Corona, Rodolfo Tuirán and Karen A. Woodrow-Lafield 1

Characteristics of Migrants: Mexicans in the United States
Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor and Paz Trigueros Legarreta 91

Factors that Influence Migration
Agustín Escobar Latapí, Philip Martin, Paul S. Davies, Gustavo López Castro and Katharine Donato 163

Impacts of Migration:
U.S. Impacts of Mexican Immigration
Michael J. Greenwood and Marta Tienda 251

Impacts of Migration in Mexico
Gustavo Verduzco and Kurt Unger 395

Responses to Migration Issues
Sidney Weintraub, Francisco Alba, Rafael Fernández de Castro and Manuel García y Griego 437

Volume 2 • Research Reports and Background Materials

Quantification of Migration

Estimating Unauthorized Mexican Migration to the United States: Issues and Results
Jennifer Van Hook and Frank D. Bean 511

Estimating Underenumeration among Unauthorized Mexican Migrants to the United States: Applications of Mortality Analyses
Jennifer Van Hook and Frank D. Bean 551

The Mexican-origin Population of the United States in the Twentieth Century
Jennifer E. Glick and Jennifer Van Hook 571

Emigration: Implications for U.S. Immigration Policy Research
Ellen Percy Kraly 587

Estimating Authorized Immigration
Karen A. Woodrow-Lafield 619

Viewing Emigration at Century's End
Karen A. Woodrow-Lafield 683

Characteristics of Migrants

The Process of Acquiring Citizenship and/or Nationality at Birth in Mexico and the United States
Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor and Paz Trigueros Legarreta 695

The Selectivity of International Labor Migration and Characteristics of Mexico-to-U.S. Migrants: Theoretical Considerations
Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor and Paz Trigueros Legarreta *699*

Data Sources
Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor and Paz Trigueros Legarreta *709*

Immigrant Characteristics from U.S. Data Sources
Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor and Paz Trigueros Legarreta *747*

Mexico-to-U.S. Migrant Characteristics from Surveys Involving Samples Drawn in Mexico
Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor and Paz Trigueros Legarreta 769

Mexico-to-U.S. Migrant Characteristics from Mexican Data Sources
Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor and Paz Trigueros Legarreta 779

Some Thoughts on Perceptions and Policies
Jorge A. Bustamante 819

Volume 3 • Research Reports and Background Materials

Factors that Influence Migration

U.S.-Mexican Migration
Philip Martin 869

Mexican Immigrant Workers and U.S. Food Expenditures
Philip Martin 871

Guest Workers: Past and Present
Philip Martin 877

Proposition 187 in California
Philip Martin 897

Mexican Migration Project Data
Katharine Donato 903

Coyotes and Alien Smuggling
Gustavo López Castro 965

Factores de la Migración y Redes Migratorias
Jean Papail 975

Impacts of Migration

The Participation of Mexican-born Households in Means-tested U.S. Welfare Programs
Paul S. Davies and Michael J. Greenwood 1001

Labor Market Implications of Mexican Migration:
Economies of Scale, Innovation, and Entrepreneurship
Michael J. Rosenfeld and Marta Tienda *1049*

The U.S. Labor Market Impacts of Low-skill Migration
from Mexico
Paul S. Davies, Michael J. Greenwood, Gary L. Hunt,
Ulrich Kohli and Marta Tienda *1075*

Mexican Immigrants and Mexican American Political
Assimilation
Michael J. Rosenfeld *1117*

Transferability of Skills and the Economic Rewards to U.S.
Employment for Return Migrants in Mexico
Steven S. Zahniser and Michael J. Greenwood *1133*

Impactos de las Cambios Económicos en el Agro Mexicano
y en la Migración: Un Análysis Micro-multisectorial

Rafael Fernández de Castro *1235*

Selected Court Cases on Immigration Enforcement
U.S. Court Decisions *1241*

On the Unrenounceability of Mexican Nationality
Sidney Weintraub *1249*

Acknowledgements

The Mexico/United States Binational Study on Migration was a joint effort undertaken by twenty scholars from both countries who worked together in teams on five separate subject areas. The subject areas and team members are listed below. These researchers wrote background research papers and individual team reports, whose information and conclusions were collaboratively condensed and compiled into a joint summary report published under the title *The Binational Study on Migration Between Mexico and the United States*. The present three-volume publication contains the individual team reports (Volume 1) and background research papers and materials (Volumes 2 and 3) that were prepared as part of the Binational Study and that constitute the basis for the joint summary. We are appreciative of the efforts of the team members who, despite their different academic disciplines and subject area expertise, worked in a productive and collegial atmosphere. The summary report, the team reports, and the background papers all demonstrate the commitment of the binational members to producing a state-of-the art assessment of many aspects of Mexico-to-United States migration.

The Binational Study was funded by both the Mexican and United States governments in conjunction with private sector funding in both countries. This

structure was created to optimize the independence of the research teams and to make the final summary report immediately available to institutions interested in the critical role of migration in the bilateral relationship. The Mexican Ministry of Foreign Affairs funded the Study and, with the Ministry of Interior, supported the work of this Study. The U.S. Congress appropriated funds coordinated by the U.S. Commission on Immigration Reform, and both the U.S. Immigration and Naturalization Service and the Department of State made contributions. We also acknowledge funding received from the Consejo Nacional de Ciencia y Tecnología and the United States Information Service in Mexico. Private sector funders were very interested in the project. The Fundación Muguel Alemán in Mexico contributed and the Ford and the Hewlett Foundations in the United States also supported the entire project.

We are grateful for the data and information supplied to the Binational Study by government institutions in Mexico and the United States. We also appreciate the commissioned analyses prepared by Mexican and American consultants to the Study.

Finally, we acknowledge the many individuals in both countries who gave of their time and assisted the Study in gaining invaluable insights above and beyond the more mundane aspects of academic research. The Binational Study alternated its meeting sites between Mexico and the United States and visited several communities in both countries. Government officials were forthcoming in sharing information and hosting opportunities to learn in Mexico City, San Diego, Tijuana, Oaxaca, Washington, San Antonio, and Chicago. The members of the Binational Study especially appreciated the frank exchanges with community residents and migrants in Tijuana, Oaxaca, Guadalajara, and Chicago.

The publication of the present three-volume set did not occur before the U.S. Commission on Immigration Reform sunset on December 31, 1997. Publication was thus subsequently undertaken by the Mexican Migration and Policy Program of The University of Texas at Austin, a joint program of the Lyndon B. Johnson School of Public Affairs and the Population Research Center, under the supervision of Frank D. Bean. The three volumes and the joint summary are also currently available electronically from *http://www.utexas.edu/lbj/uscir*. Special thanks are owed to Anne Isenhower, without whose Herculean and well-organized efforts this project would not have been completed. José A. Arréllaga Acosta, Maria McGivney Arréllaga, Marlena Crusere, Eve Kleinman, Raquel Marquez, Nancy Meredith, Terry Sherrell, and Ruth Whitenton also provided valuable assistance. Other members of the staff of both the LBJ School and the Population Research Center also helped in the publication of these volumes, for which the Binational Study wishes to express its gratitude.

FACTORS THAT INFLUENCE MIGRATION

U.S.-Mexican Migration

Philip Martin

Mexico hosts a significant foreign population—some 440,000 foreigners were registered with the National Migration Institute as permanent residents of Mexico in 1995, including 150,000 U.S. citizens.[1]

There is a significant migration between the U.S. and Mexico. Most U.S.-Mexican migration involves Mexican citizens who are returning after seasonal employment in the U.S. In addition, it is believed that many legal Mexican immigrants return to settle in Mexico—return migration may be equivalent to 20 to 30 percent of annual Mexican immigration. Finally, some U.S. citizens—many of Mexican origin—move to Mexico each year, especially after they retire from their U.S. jobs. There were reportedly 150,000 U.S. citizens registered with Mexico's National Migration Institute as permanent residents of Mexico in 1995.

There are also temporary foreign workers in Mexico grouped, as in the U.S., at the extremes of the job ladder. According to press accounts, Mexico issues about 125,000 work permits to foreign workers each year, mostly seasonal permits for Guatemalan farm workers, and there are reportedly "thousands" more unauthorized foreign workers in Mexico (Migration News, January, 1995), including many unskilled Central Americans employed at the bottom of the Mexican labor market picking coffee beans, doing unskilled construction work, or employed in Mexican households as maids and gardeners.

Many of the factors that sustain Mexico-U.S. migration also sustain Central American-Mexican migration, viz, Mexican labor markets that have become dependent on Guatemalan and other foreign workers, workers pushed across the border by significant wage and unemployment gaps, and networks of friends, relatives, and labor contractors who can bridge the border. Early in 1996, it was reported that Mexico was apprehending an average 300 Central Americans and Asians per day, double the number in 1995 (Migration News, January 1996).

There were in 1994 reportedly thousands of professional foreign workers in Mexico, including both legal and illegal "dryback" Americans. Unlike most other Western Hemisphere visitors, who get 30 day tourist visas, Mexico issued 2 million Americans 6 month tourist visas in 1993.[2] Americans who live in Mexico can then simply cross into the United States every 6 months, and get a new tourist visa on their return to Mexico.[3]

The U.S. Department of State estimated that, as of May 1, 1993, some 2.6 million U.S. citizens lived abroad, including 522,000 in Mexico, 335,000 in Canada, 215,000 in the United Kingdom, 160,000 in Germany, 131,000 in the Philippines, 125,000 in Israel, and 103,000 in Italy (Bratsberg and Terrell, 1996, 791).

Notes

1. In the 1990 Mexican Census, some 300,000 residents of Mexico were reportedly born in another country, and 600,000 did not specify a country of birth.

2. In 1994, an estimated 17 million U.S. residents visited Mexico, and they accounted for about three-fourths of Mexico's $7.5 billion tourism revenues.

3. Some U.S. residents of Mexico report that it is easier to live and work "illegally" in Mexico by manipulating tourist visas than it is to obtain the proper residence visa. Americans doing business in Mexico are granted 30-day business visas, and they must prove that they are affiliated with an established U.S. or Mexican company, and that they are not displacing equally-qualified Mexicans, to obtain a longer business visa. American retirees who want to register as Mexican residents must have an income of at least $2,000 a month.

FACTORS THAT INFLUENCE MIGRATION

Mexican Immigrant Workers and U.S. Food Expenditures

Philip Martin

U.S. Food Expenditures

There were about 100 million "consumer units" in the U.S. in 1993, and they spent an average $30,700, up from $29,800 in 1992. The U.S. population in 1993 was 258 million, so the average consumer unit contained about 2.6 persons.

The five largest expenditure items in 1993 were housing, $9600, transportation, $5500, food, $4400, personal taxes, $3000, and personal insurance and pensions, $2900.[1]

Food expenditures included $2700 for food eaten at home, 9 percent of total expenditures, or about $52 per week. The major items consumed at home were meat and poultry, on which spending averaged $735, fruits and vegetables, $445, cereals and bread, $435, and dairy products, $295. In addition, consumer units spent an average $225 on non-alcoholic beverages, and $270 on alcoholic beverages.

About 60 percent or $270 of the fruit and vegetable expenditures were for fresh fruits and vegetables—about $135 for fresh fruits, and $135 for fresh vegetables, the commodities most likely to use immigrant farm labor. Over 52

weeks, this means that the average consumer unit spent $5.20 per week on fresh produce.

Farmers obtained an average 24 percent of the retail price of food consumed at home in 1993—or about $650. The farmer's share of the retail food dollar ranged from a low of about 7 percent for grains used in cereal and bakery products, to 40 to 48 percent for poultry, eggs, and beef.

Farmers received about 19 percent of the average retail price for fresh fruits ($26 of $135), and 23 percent of the retail price of fresh vegetables ($31 of $135), so that farmers get $57 or 21 percent of the $270 average retail expenditures on fresh fruits and vegetables. Farm labor, including supervisory labor, typically represents about one-third of farmers' costs of production for fresh fruits and vegetables, or farm labor represents about $8.60 of the $26 that the average U.S. consumer unit spends on fresh fruit, and $10.20 of spending on fresh vegetables, or a total $19 per consumer unit per year.

Suppose that current levels of immigration hold farm wages 50 percent below the level they would otherwise be, so that current farm worker wages of $5 to $6 per hour would be $7.50 to $9 per hour without additional immigrant workers. And suppose that the entire cost of higher farm wages is passed through to consumers, so that the annual cost of the farm labor used to produce the fresh fruit consumed by the average American household rises from $8.60 to $13, and the cost of farm labor to produce fresh vegetables rises from $10.20 to $15.

If these increased farm labor costs were completely passed through to consumers, spending on fresh fruits and vegetables eaten at home for a typical 2.6 person consumer unit would rise by almost $10, from $270 to $280.

In addition to food eaten at home, the average consumer unit in 1993 spent $1700 on food eaten away from home. It is difficult to calculate the food cost of meals eaten away from home—some of the total cost of restaurant, cafeteria, and airline meals reflects services and atmosphere. If 10 percent of away from home food is for fresh fruits and vegetables, another $170 is spent on them, and if the farm share of fresh produce eaten away from home is 21 percent or $36, and if farm labor represents 33 percent or $12 of this farm share, then a 50 percent increase in farm labor costs would raise spending on fresh fruits and vegetables eaten away from home by $6, from $170 to $176.

The total increase in average consumer unit spending on food if farm wages were to rise by 50 percent as a result of immigration changes, and if all of the increased costs were passed through to consumers, would be about $16 per year. For 2.6 persons, 50 percent higher farm wages would increase individual produce expenditures by $6.

In 1995, the average American ate 712 pounds of fruits and vegetables. About 40 percent or 285 pounds are consumed as fresh produce—including almost 50

pounds of potatoes per person. Consumer units in the Northeast and Midwest spend more on average for fresh fruits and vegetables, as do larger consumer units and those with higher incomes.

Mexican immigrants play important roles throughout the U.S. food and fiber system, so that focusing on fresh fruits and vegetables understates their importance. However, the combination of a small farm share of retail food prices, and a relatively small share of hired labor in farm production costs—in 1992, 98 percent of the 1.9 million U.S. farm operators were non-Hispanic whites—means that farm wages lowered by immigration do not make food and fiber much cheaper for consumers.

For example, in 1993, U.S. farmers paid wages and benefits of $12 billion to farm workers that they hired directly, and an additional $3 billion to contractors to cover the cost of worker wages and benefits as well as contractor profits. The value of farm commodities sold in 1993 was $175 billion—$90 billion in livestock sales, and $85 billion in crop sales.

This means that total labor expenditures were about 8.6 percent of farm sales and, since farmers, on average, obtain about 25 percent of retail expenditures, a $1 purchase at the grocery store includes $0.25 for the farmer, and $0.02 for farm workers.

The Tomato and Raisin Cases

Much of the debate over whether a new guest worker program is needed for U.S. agriculture is a debate over how the farm labor market would adjust if the 20 to 40 percent of the work force that is believed to be unauthorized were prevented from working by stepped up border and interior controls.

According to U.S. farmers, if there are currently 100 workers employed, and 30 are unauthorized, then effective immigration controls would require the growers to find 30 new workers. Since, growers assert, these new workers are not available within the U.S., even at higher wages, growers should have easy access to foreign workers.

Worker advocates counter that the supply of U.S. workers is elastic—at higher wages, more U.S. workers would seek farm jobs, or remain farm workers.

But the history of the U.S. suggests that the key factor in adjusting to fewer workers is the **demand** for labor, not the supply. When wages rise, growers typically find ways to get work done with fewer workers, so that the labor force in agriculture shrinks.

This section reviews two cases: the actual adjustment of processing tomatoes to the end of the Bracero Program, and the likely adjustment of the raisin grape industry to fewer migrant workers.

Tomatoes

In 1979, The California Agrarian Action Project filed suit against UC on behalf of 19 farm workers, charging that university research used public funds to, inter alia, displace farm workers and eliminate small farmers (Superior Court of California, Case 516427-5, September 4, 1979). The federal and state governments were, in the mid-1980s, spending $1 billion per year of public monies on agricultural research, and the suit asked that UC mechanization research be halted until the university created a fund to assist farm workers equal in size to what UC earns from royalties (Martin and Olmstead, 1985, 601).

This "mechanization lawsuit" turned the spotlight on the major U.S. employer of Bracero workers in the early 1960s, and illustrates how the one case of adjustment to fewer Mexican workers in fact occurred. In 1960, a peak 45,000 workers—80 percent of whom were *braceros*—hand-picked 2.5 million tons of the processing tomatoes used to make catsup in California. In 1990, about 5,500 mostly female farm workers were employed to sort 4 times more tomatoes[2] (Mamer and Wilke, 1990). In this case, mechanization reduced the number of jobs for farm workers, and changed the harvesting task from hand-picking tomatoes into field boxes to riding on a machine and sorting machine-picked tomatoes.

In 1960, all processing tomatoes were picked by hand. In 1970, none were. How reliable were the mechanization forecasts of those in the tomato industry? A 1963 report by the Giannini Foundation of Agricultural Economics concluded that, if Bracero tomato pickers were not available, the CA industry would shrink, and that many growers may follow their pickers to Mexico, which would lead to job losses in associated canning and processing. Senator Kuchel (R-CA), representing CA growers, asserted that mechanizing the tomato harvest was "feasible, but 8 to 10 years away" (Congressional Record, August 15, 1963, 15205).

Raisins

The single most labor-intensive activity in North America in the mid-1990s is harvesting raisin grapes. Some 40,000 to 50,000 workers are involved in a four to six-week effort to cut bunches of grapes from 200,000 acres of vines—owned by 5500 small farmers—and lay them on paper trays to dry in the sun (Alvarado, Mason, and Riley, 1995, 379). Many of the workers are recently-arrived and thus unauthorized, and the presumption is that the centuries-old process of paying workers $0.15 to $0.18 per 25-pound tray of grapes picked and laid on paper trays to dry in the sun—in 1995—cannot be changed.

A case study of the raisin industry in the early 1990s noted that the interaction of a "continued and unabated influx" of immigrant workers to replace SAWs, non-enforcement of employer sanctions, and the use of labor contractors to match workers

and jobs left the 94 percent Mexican-born labor force working under some of the "most marginal conditions" in California agriculture sun (Alvarado, Mason, and Riley, 1995, 379-80). Virtually all of the labor contractor-grower arrangements are verbal agreements to have the labor contractor take responsibility for finding and supervising a crew of workers in exchange for a flat fee, a median $0.21 per tray in 1991, or to pay the contractor the agreed upon piecerate to harvest workers—$0.15 to $0.18 per tray—plus 31 percent for payroll taxes and the contractor's expenses and profits (Alvarado, Mason, and Riley, 1995, 383).

There are methods to harvest raisins and other commodities with machines, or to use machines to save much of the labor currently employed in the raisin harvest. One grower, for example, planted twice the number of raisin vines per acre, cut the canes by hand to let the raisins dry on the vine, and then harvested the dried-on-the-vine raisins mechanically—with a machine developed to pick wine grapes at night and thus improve grape quality—by shaking the raisins off the vines.[3] A variety of machines to eliminate most of the hand-harvest labor in raisins are available, at costs ranging from $20,000 to $100,000.

The conventional raisin harvesting system requires an ample supply of workers without other U.S. job options—many of the raisin growers interviewed in 1991 said that they would switch to mechanical raisin grape harvesting if there were a labor shortage. This suggests that, in the raisin case, improving wages and benefits would reduce the demand for labor. The mechanical system, according to the grower who uses it, relies on a handful of well-paid workers (Dan Bryant, "Grower finds the benefits outweigh drawbacks with dried-on-vine raisins," Ag Alert, December 20, 1995).

Notes

1. These food expenditure data are from the Statistical Abstract of the U.S., 1994, 465.

2. There are no consistent data on farm worker employment by commodity. One way to estimate employment by commodity is to ask farm advisors to estimate the hours of regular and seasonal labor required per acre to produce a commodity. This approach was used to generate these employment estimates, but they include often unexplained differences for the same commodity that is produced similarly in 2 counties.

Mamer and Wilke (1990), for example, report that the 40,000 acres of processing tomatoes in Yolo county required 6 regular and 38 temporary hours of labor per acre in 1989, while the 63,000 acres in Fresno county required 22 regular and 31 seasonal hours. These numbers were combined to generate a statewide average 16 regular and 34 seasonal hours per acre.

The major reason for the difference in hours is that in Yolo county, irrigation hours were reported to be 0, while in Fresno, they were 7 hours per acre. The Fresno report also included 5 hours of regular supervisory labor per acre, while the Yolo report had none.

Both county reports estimated that harvesting required 11 to 13 hours per acre, or that harvesting required fewer hours per acre than thinning and weeding (14 hours). At 12 hours

per acre, sorting the tomatoes from California's 330,000 acres in 1990 required 4 million hours of labor. Sorters sometimes work 12 hours per day and 6 day weeks; if they average 72 hours weekly for 10 weeks, they average 720 hours per season. These calculations suggest that a total 5500 sorters would be required; at the usual wage hourly wage of $4.50 in 1993, sorters average $3240 each.

3. Drying raisins on the vine raises yields—high density plantings are expected to be five to six tons of raisins per acre, versus two to 2.5 tons per acre for conventional raisins.

Factors that Influence Migration

Guest Workers: Past and Present

Philip Martin

The Bracero Program

There were three major phases of U.S. government-authorized recruitment of Mexican workers, and each was associated with a wartime emergency. However, "the Bracero Program" usually refers to the agreements between the U.S. and Mexico that permitted 4.6 million Mexican farm workers to enter the United States on a temporary basis to do farm work between 1942 and 1964. Some workers returned year after year; an estimated one to two million Mexicans worked seasonally in the U.S. over these 22 years.

World War I Programs

Between 1885 and 1952, there was no U.S. law that permitted the admission of temporary foreign workers—immigrants had the right to work where they pleased, so that they could not be confined e.g., to a particular employer or to seasonal agriculture. Indeed, the Immigration Act of 1917 went even further, explicitly denying admission to "persons... who have been induced... to migrate to this country by offers or promises of employment," thus preventing the entry of immigrant workers who were recruited to work for particular employers. The 1917 Immigration

Act also imposed a head tax on immigrants and excluded immigrants over 16 who could not read in any language.

The first U.S. government-approved recruitment of Mexican workers occurred in 1917, when the U.S. Department of Labor suspended the contract worker bar, head tax, and the literacy test for Mexican workers coming to work for U.S. farmers for up to one year. Many Mexicans had left the U.S. in the spring of 1917, in part because of rumors that Mexicans would be drafted into the U.S. army, and to replace them, as well as to replace U.S. residents who were drafted, Mexicans were legally admitted.

Mexicans coming to the U.S. under this first Bracero Program had to provide two photos, one for the INS and one for a card that the Mexican worker carried with him, and pay their own transportation to the U.S. Housing and meal arrangements were left to the discretion of employer-worker arrangements and, as a result, some Mexican workers wound up owing money at the end of the season.

Between May 23, 1917 and June 1920, some 51,000 Mexicans entered the United States legally under these exemptions, and 80 percent were farm workers (Fuller, 1942, 19853). Another source reports that 80,000 Mexican workers were admitted between 1917 and 1921, mostly to work "in the sugar beet fields of CA, CO, UT, and ID, and in the cotton fields of TX, Arkansas, and CA" (Scuggs, 1960, 322).

The Mexican workers had to pay for their own round-trip transportation to the U.S., and many lived in farmer-owned housing and bought food from their farmer-employers. Wages were set by farmers, and there was no U.S. government enforcement of farmer wage promise. In some cases, Mexican workers wound up owing their farmer-employers money, and the Mexican government, forced to deal with the repatriation of "stranded" workers, amended its labor law in 1931 to require that foreign employers must pay the round-trip transportation expenses of Mexican workers.

Farmers during World War I did not necessarily want Mexicans: California fruit growers in 1917 approved a resolution that requested, "as a war measure, to permit the introduction of sufficient Chinese or other farm labor... to feed our Allies and prevent them from being starved into surrender" (California Farmer, December 8, 1917). The Los Angeles Times in 1920 was quoted as calling for Chinese farm workers; "who would be injured if 1,000,000 Chinamen were brought to this country to work on the farms or where needed...?" (quoted in California Cultivator, January 17, 1920). An influential survey of farm labor problems in 1918 noted that "Chinese or Orientals" were preferred to Mexicans (Adams and Kelly, 1918, 9).

Many Mexicans were eager to migrate. During the Mexican Revolution (1913-1920), the seven west central states of Mexico—Nuevo Leon, Tamaulipas,

Zacatecas, San Luis Potosi, Guanajuato, Jalisco, and Michoacán—were a battleground between the central government in Mexico City and revolutionaries from Mexican states near the U.S. border. The fighting led most haciendas to reduce their employment. Between 1910 and 1930, by one estimate, 20 percent of the population of the west central states left, including 1.5 million, or 10 percent of Mexico's entire population, who migrated to the United States (Cross and Sandos, 1981, 9-10).

During the 1920s, when the U.S. Border Patrol was established and immigration from the Eastern Hemisphere was limited by national origin quotas, farmers persuaded Congress not to limit immigration from Mexico. Studies and testimony during the 1920s is cited frequently as examples of how farmers thought about labor; "fluid casual labor is [the] farmer's only salvation... the prime necessity of his success... Until Thomas Edison or Henry Ford develop machinery... The Mexican immigrant fills the requirements of farm labor in California and the Southwest as no other laborer could" (Survey, 1928, 8-10). Most U.S. observers agreed with the statement of one Texas Congressman in 1926—"80 percent of the Mexicans that come over for temporary work go back" (Survey, 1928, 13). Farmers asserted that Mexicans have "neither desire nor ambition to become permanent fixture(s) or citizen(s)" (Survey, 1928, 17).

World War II Programs

Repatriations and depression practically stopped Mexico-U.S. migration in the 1930s. During the 1930s, there was an outpouring of literature about the misery caused by a surplus of farm workers, especially in California.

The Depression brought approximately 1.3 million people from other states to California, and at least 150,000 of these new Californians became farm workers. U.S. citizens had been part of California's seasonal farm work force since the 1850s, but it was only in the 1930s that they played the usual role of immigrants—the newest and most desperate additions to the farm work force. Both California farm employers and farm workers complained that too many workers were trying to find farm work, and researchers began to use the term "open-air food factories" to describe large CA farms that hired gangs of farm workers for short harvest periods (Taylor and Vasey, 1936, 419).

The year 1939 was the high water mark of publicity and concern about farm labor problems in California. John Steinbeck asked in *The Grapes of Wrath* how one group of Americans could take such undue advantage of other Americans who were temporarily down-on-their-luck. Carey McWilliams wrote *Factories in the Fields,* and Varden Fuller's thesis, *The Supply of Agricultural Labor as a Factor in the Evolution of Farm Organization in California,* demonstrated that

California farms had more in common with the non-farm factories that were being subjected to federal labor laws than the family farms described in Congressional debates to demonstrate that hired farm workers did not want or need the protections of labor laws.

These reports convinced most Americans that California agriculture was different, and that the labor law protections that had been made available to non-farm workers should be extended to workers on at least the largest farms. However, this reform zeal never took root. War intervened, and some of the young men who may have been active union organizers joined the armed forces, and other men and women found factory jobs. Instead of reforming farm labor markets to make farm jobs acceptable to American workers, the wartime emergency was used to justify the importation of Mexican Bracero farm workers.

In the spring of 1942, California farmers predicted that there would be labor shortages, and they called for the importation of between 40,000 and 100,000 Mexican farm workers for the September harvest. On July 23, 1942, the U.S. and Mexican governments concluded a "farm labor supply agreement" that permitted Mexican workers (*braceros*) to enter the U.S. do farm work on emergency basis when U.S. workers were not available. On September 27, 1942, the first *braceros* entered the U.S. in El Paso, en route to California sugar beet fields.

Reformers complained bitterly that there was no shortage of farm workers. Growers' cries of labor shortages were, they argued, "a mere repetition of the age-old obsession of all farmers for a surplus labor supply" (Craig,1971, 38-39). And many farmers had reservations about the Bracero Program, since it required that a minimum wage of $0.30 per hour be paid, and that Bracero workers be guaranteed work for three-fourths of the period that the farmer promised them work. Farmers feared that such minimum wages and work guarantees would spread from foreign to domestic workers, and so no Texas farmers requested *braceros* in 1942.

The Mexican government, sensitive about the conditions under which some of its nationals had previously worked in the U.S.[1] and, according to Craig, doubtful that there was a real labor shortage in U.S. agriculture, insisted that the U.S. government guarantee the contracts that farmers provided to Mexican workers, including round-trip transportation and the payment of wages equal to those of similar American workers (Craig, 1971, 41). The U.S. government agreed, and Mexican workers were admitted to the United States by establishing an exception to immigration laws for "native-born residents of North America, South America, and Central America, and the islands adjacent thereto, desiring to perform agricultural labor in the United States."

The 1942 agreement allowed *braceros* to bring their families to the U.S., a provision that U.S. employers wanted so that fewer *braceros* would desert their

contracts, and so that spouses and children 14 and older could work. However, no family members of *braceros* were admitted (Congressional Research Service, 1980, 24).

The Bracero Program was small during the war years; admissions peaked at 62,000 in 1944, less than 2 percent of nation's 4 million hired workers. However, *braceros* were concentrated on a few farms in a few states, where their impacts were significant. *Braceros* were employed primarily in the southwestern states, with the majority employed in California, and then only on the largest farms—fewer than 50,000, or 2 percent of the nation's commercial farms, ever employed Braceros. Although the major crop changed during the life of the program, most Braceros picked cotton during the program's first years.

Both the U.S. and Mexican governments hoped that the opportunity to migrate legally would reduce the illegal flow of Mexican workers to the U.S. However, Scruggs concluded that, "the Bracero Program, instead of diverting the flow of wetbacks into legal channels... actually stimulated unlawful emigration" (1961, 151). But Mexico did not send Braceros legally to Texas, and so many Mexicans went illegally to Texas and other states. The Mexican foreign minister on August 8, 1946 suggested that, if the U.S. were to impose "sanctions on American employers who employ illegal entrants, the result would promptly come about that Mexican workers would not in the future" migrate illegally (Congressional Research Service, 1980, 26).

The Bracero Program with the U.S. government as the contractor of Mexican workers lapsed on December 31, 1947, and there followed several years of a constantly revised agreement, but the flow of Mexican workers northward was mostly informal and unlawful. Beginning in 1948, the U.S. employer, not the U.S. government, was the legal contractor of Mexican workers, and the U.S. employer was responsible for paying the Mexican worker's round trip transportation, and the U.S. Employment Service became responsible for certifying that U.S. workers were not available.

Illegal immigration increased in the late 1940 as Braceros learned they did not have to pay bribes to local Mexican officials to get on recruitment lists, and then pay additional bribes at recruitment centers. U.S. farmers were pleased because they could employ Mexican workers without government "red tape," such as having their housing for Braceros inspected and being required to offer them the minimum or government-calculated prevailing wage, whichever was higher. American workers protested that Braceros were being used to break their strikes, as occurred during the 1947 strike of table grape harvesters at DiGiorgio farms in 1947 (Pollit, 1971, 67).[2]

The number of aliens who were legalized after arriving and finding employment illegally far exceeded the number of Mexican workers that U.S. employers

contracted legally in the interior of Mexico. Between 1947 and 1949, for example, 74,600 Mexicans received contracts from U.S. employers at recruitment centers inside Mexico. By contrast, 142,000 "wetbacks" who were illegally in the U.S. were legalized by granting them contracts, a process termed, even in official U.S. government publications, as "drying out the wetbacks" (President's Commission, 1951, p. 53).

The President's Commission on Migratory Labor, established in 1951, was asked to investigate whether Braceros were adversely affecting U.S. workers, and whether additional Mexican workers were needed because of the Korean War emergency. The President's Commission concluded that:

- Bracero labor "depressed farm wages and, therefore, has been detrimental to domestic labor"
- Mexico rather than the U.S. "secured reasonable limitation of numbers and some protection to labor standards"
- "foreign labor importation... should be under the terms of intergovernmental agreements which clearly state the conditions and standards of employment" (President's Commission, 1951, 64-66).

Furthermore, the Commission concluded that "no special measures be adopted to increase the number of alien contract workers beyond the number admitted in 1950," which was 67,500, and that "legislation be enacted making it unlawful to employ aliens illegally in the United States" (President's Commission, 1951, 178).

Korean War Programs

The President's Commission recommendations were not adopted. On July 12, 1951, PL-78, the Mexican Farm Labor Program, became law (Craig, 1971). PL-78 amended the Agricultural Act of 1949 to authorize the U.S. government to negotiate an agreement with Mexico to admit Mexican workers to work seasonally in "essential" U.S. crops until December 31, 1953.

The U.S. Department of Labor administered the program from the U.S. side, by notifying Mexico at least 30 days before Braceros were needed, and then operating reception centers on the border, arranging transportation from the reception centers to U.S. farms, helping Mexican workers and U.S. farmers to negotiate contracts covering wages and working conditions, and enforcing these contracts. Farmers had to reimburse the U.S. government for its costs, up to $15 per worker, and pay an additional fee if the Bracero was not returned to the reception center at the end of the contract. Farmers were expected to pay all the costs associated with PL-78 Braceros except for enforcement costs.

The U.S. Secretary of Labor was prohibited from supplying Mexican workers to U.S. employers unless DOL certified that there were not sufficient domestic workers who were "able, willing, and qualified" to do the work after "reasonable" recruitment efforts, and that the presence of Mexican workers would not "adversely affect the wages and working conditions of domestic agricultural workers similarly employed."

The program operated with the U.S. Department of Labor notifying Mexico 30 days in advance of the number of Mexican workers likely to be needed. The Mexican Interior ministry contacted governors of Mexican states "where Braceros are available"—each Mexican state had a Bracero quota that was to be based on unemployment rates.[3] The governor, in turn, contacted mayors, who "select Braceros from a waiting list on a first-come, first-served basis" (Taylor, 1963, 42).

The Braceros selected had provided their own transportation to one of three reception centers in Mexico—in Ciudad Chihuahua, Empalme, Sonora, and Monterrey, Nuevo Leon—these Mexican reception centers were an average 280 miles from the U.S. border.[4] At these reception centers, Braceros were interviewed to determine if they had farm work experience, examined by Mexican doctors under contract to the U.S. Public Health service for their ability to do farm work, and then checked by the INS for their admissibility as non-immigrants. Mexican workers then received conditional entry permits that permitted them to report to one of several U.S. reception centers on the border, in El Centro, Nogales, El Paso, and Hildalgo.

At these U.S. reception centers, farmers and associations "contracted" Mexican workers, usually by having an association representative sign the contract on their behalf, and then the Bracero, and representatives of the U.S. and Mexican governments, signed as witnesses. Most Braceros were "repeaters"—a survey of 309,000 Braceros in the second half of 1957 found that 78 percent had worked as Braceros at least one year before, and 22 percent were first-time Braceros.

DOL noted that, because of the "volume of workers," it is "impractical to select individuals in response to employer requests" (U.S. Department of Labor, 1953, 7). Braceros were not subject to Social Security or income taxes.

Farmers in most cases offered first-time Braceros minimum six-week contracts, and then offered renewals to Braceros deemed satisfactory (Anderson, 1961). Maximum contracts were for six months, with extensions of at least six week intervals possible. Bracero workers could be "furloughed" without pay for up to 15 days during the life of the contract.

Each worker-employer contract had to include provisions that DOL and the Mexican government required, including the promise to pay the higher of the prevailing or adverse effect wage at least every two weeks, a guarantee of work for at

least three-fourths of the work days in the contract period, free housing that was to be inspected by DOL, either meals provided at cost by the employer or cooking facilities, and workers' compensation insurance to cover expenses if the Bracero was injured at work. At the end of the contract, Braceros were to be given money to cover their transportation and subsistence back to the reception center—they were expected to check in within 5 days of the end of the contract. However, if the Bracero abandoned his job, or did not "give his employer reasonable opportunity to provide transportation," the employer was not required to pay return transportation and subsistence.

Some of the proponents of the Bracero Program argued that the possibility of legal entry would reduce illegal immigration. President Truman, in reluctantly signing PL-78 into law, sent a note to Mexican President Aleman suggesting that the Bracero Program be only six months long to keep up the pressure on Congress to approve an employer sanctions bill.

President Aleman agreed that the U.S. and Mexico should combine "our efforts, in putting a definite stop to the illegal movement of agricultural workers" (quoted in Kiser and Kiser, 1979, 157). In 1951, Mexico's interior ministry announced that it was "adopting new measures to have our border authorities keep a strict vigilance over the departure of our compatriots and prevent the departure of those who are not properly documented," and cooperating with defense and other ministries to "prevent the illegal departure of our compatriots from Mexican Territory" (Kiser and Kiser, 1979, 159-160).

However, in Congressional debate over what became the Immigration and Nationality Act of 1952, an amendment in the Senate to penalize U.S. employers found to employ illegal aliens when the employer had "reasonable grounds to believe a worker was not legally in the U.S." was defeated by a vote of 69-12. Instead, the so-called Texas proviso was included in the INA—the willful importation, transportation, or harboring of illegal aliens became a felony punishable by fines of up to $2000 or five years imprisonment, but "employment of an illegal alien" was specifically exempted from the definition of harboring.

Illegal immigration continued after PL-78 was signed: a Life magazine story entitled "Wetbacks Swarm In" was typical of the era. The Border Patrol had been reduced to 1,000 agents by 1953 and, the U.S. Attorney General pronounced himself "shocked" by the extent of illegal immigration in August 1953. A former General of the Sixth Army was appointed INS Commissioner in the spring of 1954, with orders to "halt the influx."

"Operation Wetback" was launched by the INS in 1954, and resulted in 1.1 million apprehensions during what was then a July 1953-June 1954 fiscal year. Most of these apprehensions occurred at the border in May and June 1954—there

were only 80,000 apprehensions during the height of the June-August 1954 interior sweeps, and most of these apprehensions were recorded in FY55.

The Bracero Program expanded to accommodate more legal Mexican workers, so that the ratio of apprehensions to Braceros was reversed; in 1951-52, there were 5 apprehensions per Bracero admission; by 1956-57, there were 5 Bracero admissions per apprehension.

There was no explicit provision that Braceros be only temporary U.S. residents, so that, by 1959, it was reported that 20,000 "specials" were employed in year-round jobs. Most of these specials received six-month contracts that were renewed, and most were employed in Texas and New Mexico (U.S. Department of Labor, 1959, 5).

The availability of Braceros permitted the southwestern states to become the garden states of the United States. In California, fruit and nut production rose 15 percent during the 1950s, and vegetable production rose 50 percent. New irrigation facilities expanded the acreage available to grow fruits and vegetables, the interstate highway system allowed produce to be shipped cheaply to eastern markets, and new plant varieties and packing technologies made California produce preferred to locally-grown fruits and vegetables in the eastern United States where most Americans lived.

This expansion of farm production in California was not accompanied by higher farm wages. The U.S. Department of Agriculture's estimate of average hourly farm earnings rose 41 percent—slightly more than the 35 percent increase in consumer prices—from $0.85 in 1950 to $1.20 in 1960. In contrast, average factory wages in California rose 63 percent, from $1.60 per hour in 1950 to $2.60 in 1960. Slowly rising farm wages and faster-rising factory wages drew American workers to factory jobs where there were no Braceros.

In addition to Mexican workers, California farmers also imported workers from Japan and the Philippines. Under a program established with Japan in 1956, some 1730 Japanese were employed in December 1960, mostly in Ventura county, and 28 Filipinos were imported, both under provisions of the H-2 program. Asian workers paid their own transportation to California, and the farmer paid their transportation from Los Angeles or San Francisco to the work site. Asian workers got 6-month renewable contracts, and most remained in California for three years (California Assembly, 1965, 9-10).

By the early 1960s, Braceros were essential to harvest only a few crops. As cotton and other geographically dispersed crops were mechanized, the Bracero Program became a non-immigrant program for a handful of farmers, and political support in the U.S. for its continuation weakened. As unions and ethnic groups called for the end of the Bracero Program, growers made familiar arguments to maintain the program: American workers were not available; without the immigrants

crops would rot and food prices would rise; and the admission of Braceros has no adverse effects on U.S. workers (California Senate, 1961).

An influential study in Los Angeles and found that almost half of the unemployed would do farm work if wages and conditions were improved (Schmidt, 1964, 27-28). According to the study, there were no "cultural barriers" to Americans doing farm work, only economic barriers.

The Kennedy Administration, which took office in January 1961, was determined to revise the Bracero Program to better protect U.S. workers by preventing Mexican workers from depressing U.S. farm wages. In October 1961, President Kennedy, "reluctantly" signing a bill to extend the Bracero Program through December 31, 1963, asserted that "the adverse effect of the Mexican farm labor program as it has operated in recent years on the wage and employment conditions of domestic workers is clear and cumulative in its impact" (Congressional Research Service, 1980, 52). Kennedy ordered the U.S. Department of Labor to "prescribe standards and to make the determinations essential for the protection of the wages and working conditions" of U.S. workers (quoted in Congressional Record, August 15, 1963, 15215).

Governor Pat Brown (D-CA) and most Congressional leaders opposed an extension of the Bracero Program. In May 1963, the House of Representatives rejected a two-year extension of the Bracero Program on a 174-158 vote, and then the Senate and House approved simple one-year extensions of the program, until December 31, 1964.

Mexico favored a two-year extension of the Bracero Program, pointing out that Braceros sent about $35 million annually in money orders through the Bank of Mexico, and that total remittances might top $100 million per year (Taylor, 1963, 42). In a June 21, 1963 note, the Mexican government asserted that the Bracero Program was "a result of the migration phenomenon... the absence of an agreement... would give rise to... the illegal introduction of Mexican workers into the United States." Craig credits this Mexican note with tipping the balance in Congress in favor of extending the Bracero Program one more year, until the end of 1964 (1971, 195-6).

Bracero Program Effects

Greencard Commuters

After the Bracero Program ended in 1964, foreign workers could still be imported under the H-2 section of the Immigration and Nationality Act of 1952, which allowed the Attorney General "after consultation with appropriate agencies of the Government" to import needed workers. Employers seeking H-2 workers to fill vacant jobs had to satisfy a double temporary provision—(1) the alien worker

was coming temporarily to the United States to perform temporary services or labor and (2) unemployed persons capable of performing such services cannot be found in this country. Thirdly, the employment of temporary foreign workers was to have no "adverse effects on U.S. workers" (Congressional Research Service, 1980, p. 59).

Many farmers expected to import Mexican workers under the H-2 provisions of the INA. However, the Secretary of Labor published regulations in December 1964 that had the effect of making it much more expensive and difficult to import Mexican farm workers under the H-2 program than it had been to import Braceros.[5] Many U.S. senators were outraged, and an effort to transfer the authority to certify the need for H-2 alien farm workers from the Department of Labor to the Department of Agriculture failed in the Senate only because the Vice-President cast the deciding vote (Congressional Research Service, 1979, p 42).

The U.S. launched efforts in the mid-1960s to find U.S. workers to replace Braceros. For example, in September 1964, Los Angeles county supervisors said that persons able to work and getting food and assistance from the county would be cut off if they refused to do farm work for $1.25 per hour, the adverse effect wage rate that had to be offered to Braceros (U.S. Senate, 1965, 19-20).

The number of migrant farm workers—most of whom were U.S. citizens—reached a postwar peak of 466,000 in 1965, and grower interest in mechanization increased so much that a major study predicted that, by 1975, if a fruit or vegetable could not be harvested mechanically, it would not be grown in the United States (Cargill and Rossmiller, 1970).

Most of the 50,000 to 60,000 Mexican immigrants admitted each year in the mid-1960s were believed to be ex-Braceros who got immigrant status as a result of a U.S. employer offering them jobs. An estimated 80 percent of the 55,000 Mexican immigrants admitted in 1962 were ex-Braceros, and most were admitted at the behest of California farmers (U.S. Senate, 1965, 22).

A 1963 article noted that, since immigrants bound for the U.S. had to prove that they would not become public charges in the U.S., most Mexican immigrants cleared the "public charge" hurdle by providing a letter from a U.S. employer offering the Mexican immigrant a year-round job. Some U.S. employers issued 25 or more letters and, in such cases, the practice was for the U.S. Department of Labor to certify that the employer could not obtain U.S. workers (Gallardo, 1963, 26). California farmers pointed out that it was simpler to get a greencard issued than it was to obtain a Bracero, since there was no housing inspection or requirement that a greencard worker be paid a government-set wage. Many farmers turned to greencard workers as a result of the activities of "consultants," who advised them not to issue more than 25 letters.

According to one report, there were 122,000 Mexican immigrants who provided occupational information between 1949 and 1961—Mexican immigration during the 1950s was 300,000. About 50,000 of these Mexican immigrants with occupations were farm workers, and 30,000 were domestic servants, mostly in California and Texas (Gallardo, 1963, 27). The Mexican ambassador in 1963 estimated that 32,000 farm workers became greencarders in 1961, and another 40,000 in 1962 (Congressional Record, August 15, 1963, 15204). A 1963 California Farmer article reported that 80 percent of the 222,000 immigrants from Mexico between 1957 and 1962 were ex-Braceros (Taylor, 1963, 43).

The Mexican government opposed the greencard program—the Alien Registration Card I-151 was green—pointing out that, while the greencarder was free to leave the farmer who got him immigrant status, greencard workers did not have the protection of wage, housing, and other protections that were included in Bracero contracts. The U.S. Department of Labor similarly testified in 1963 that greencard Mexicans could be used to break strikes, while Braceros could not (Congressional Record, August 15, 1963, 15187).

In 1967, the INS issued regulations that barred the use of a greencard to enter the U.S. to take up employment where a labor dispute was in progress, a response to UFW and other union complaints that greencard workers were being used to break U.S. strikes. In 1968, Senator Edward Kennedy (D-MA) introduced a bill, S2790, that would have required the U.S. Secretary of Labor to determine whether immigrants returning from temporary stays in Mexico or Canada would have an adverse effect on the wages and working conditions of U.S. workers.

Illegal immigration after the Bracero Program ended in 1964: some 110,000 deportable aliens were located in FY65, and almost twice as many, 212,000, in FY68. The number of aliens apprehended almost doubled again, to 420,000, in FY71, and then rose to 788,000 in FY74. In FY68, it was reported that 41,425 illegal Mexican aliens were apprehended while employed in U.S. agriculture (U.S. Senate, 1969, 64).

Economic Effects

There were a number of mid-1960s studies of the effects of ending the Bracero Program on U.S. agriculture and U.S. farm workers, and most came to conclusions similar to those reached by Martin in 1966, viz, that "U.S. agriculture is perfectly able to adjust to a situation without foreign labor without any major production decreases" (1966, 1137). There were $44 billion worth of farm commodities sold in 1965, and losses due to lack of labor for harvesting were estimated to total $17 million, or less than one half of one percent, with most of the losses in California strawberries (1966, 1141).

The 1996 Gallegly-Pombo Guest Worker Proposal

The House on March 21, 1996 rejected by a 242-180 vote an effort by growers to launch a new guest worker program. On March 5, 1996 the House Agriculture Committee approved 25 to 14 an amendment by Rep. Richard Pombo (R-CA) to the House immigration bill that would grant temporary work visas to 250,000 foreign farm workers, with the ceiling to be reduced by 25,000 each year.

The existing temporary farm worker program admitted about 11,400 H-2A farm workers in FY95, including 6100 Mexicans and 4200 Jamaicans, down from 13,200 in FY94, when 6100 Mexicans and 5900 Jamaicans were admitted. The largest group of Mexican H-2As is employed in North Carolina-Virginia tobacco. The Jamaicans were concentrated in the East Coast apple harvest and the Florida sugarcane harvest—U.S. Sugar, the nation's largest employer of H-2A temporary foreign workers for the past 50 years, announced in June, 1995 that it would harvest all of its sugar cane by machine in 1996. U.S. Sugar employed 1,300 Jamaican cane cutters in 1995.

Background

In February 1995, the National Council of Agricultural Employers released a proposal for a supplementary foreign worker program to fill temporary or seasonal U.S. jobs. One year later, Rep Elton Gallegly (R-CA) unveiled the NCAE proposal as the "Alternative Agricultural Temporary Worker Program" or "Temporary Agricultural Worker Amendments of 1995... to provide a less bureaucratic alternative for the admission of temporary agricultural workers."

There are about two million workers employed at some time during a typical year on the nation's crop farms, and the DOL National Agricultural Workers Survey estimates that 25 percent may be unauthorized.

Under the Gallegly-Pombo proposal, growers, labor contractors, or associations wanting to employ foreign farm workers would have had to file at least 25 days before the job was to begin a labor condition attestation (LCA) with their state Employment Service office listing the number of foreigners requested and when work was to begin. Local ES offices would review these LCAs "only for completeness and obvious inaccuracies" within seven days after they were filed. Employers violating their attestations or program rules could be assessed civil money penalties, and be barred from the program.

If the foreign workers the employer wanted to hire were outside the U.S., growers would submit their names to INS and consulates abroad, and these named workers would have been given H-2B visas to enter the U.S. at the consulates or at a port of entry. Growers could recruit foreign workers anywhere and in whatever manner they

wished. Foreign workers would have to leave the U.S. when their jobs end or be subject to deportation, unless another employer promises to hire them within 14 days.

Under the rejected plan, 25 percent of the foreign workers' wages would have been placed into a federal trust fund managed by the INS, which foreign workers would have reclaimed with interest in their country of origin. Foreign workers would have been limited to a maximum two years in the U.S. [Greg Schell of Migrant Farmworker Justice Project in Belle Glade, Florida asserted in early 1996 that 25 percent of the H-2A workers do not return to their countries of origin.]

Program costs would have been financed by employer contributions equivalent to the Social Security and unemployment insurance taxes that would not be paid by growers. Most predictions were that farmers would request the maximum 250,000 guest workers because there was no incentive not to make requests for foreign workers.

The guest worker program would sunset after three years if Congress failed to re-authorize the pilot five-state telephone verification system that the Smith bill establishes to make it easier for employers to determine whether workers are presenting false documents.

The Gallegly-Pombo proposal was essentially an effort to extend the procedure used to admit H-1B temporary foreign professionals to agriculture. Under the current H-1B program, nonfarm U.S. employers "attest" that they are paying prevailing wages and satisfying other conditions so as to have no adverse effects on similar U.S. workers—workers with at least a BA or equivalent—and then the U.S. Department of Labor relies on complaints from U.S. workers and other employers to investigate charges that employers are violating their attestations. H-1B foreign workers can remain in the U.S. for up to six years.

The current H-2A program, by contrast, requires farm employers wishing to employ H-2A temporary foreign workers to take a series of steps to prove that U.S. workers are not available, and then to offer U.S. and foreign workers housing at no cost, contracts that guarantee work for at least three-fourths of the period that the employer asserts workers are needed, and other benefits and protections.

Rep. Lamar Smith (R-Texas), chair of the House Immigration Subcommittee, argued against the growers' guest worker proposal: "once you admit hundreds of thousands of people like this, why not just pull the Border Patrol off the border and let people in?" The Clinton administration opposed the program for fear that it would increase illegal immigration, reduce job opportunities for U.S. workers, and depress wage and work standards for U.S. workers. The Clinton administration also opposed the Gallegly-Pombo, arguing that the current H-2A program is sufficiently flexible to cope with any farm labor shortages.

About 60 farm organizations, from the American Farm Bureau Federation to the Wisconsin Christmas Tree Producers sent a letter to senators and representatives

on February 12,1996 to urge the inclusion of the Gallegly proposal in immigration reform legislation.

Fourteen organizations, from the American Friends Service Committee to the United Methodist Church sent a letter to House Speaker Gingrich on February 14, 1996 opposing the Gallegly proposal, and the effort to include it in the immigration bill without hearings on its features.

On the same day, March 21, 1996, that the House rejected the Gallegly-Pombo proposal, it also voted 357-59 to reject an alternative offered by Rep Robert Goodlatte (R-VA) as a way to defeat Gallegly-Pombo. Goodlatte's proposal would have modified the H-2A program by transferring it from the Labor Department to the Immigration and Naturalization Service, reducing the required period of grower recruitment to 20 days, and capping H-2A admissions at 100,000 per year.

Congressional Hearings: 1995-96

In September and December 1995, the Senate and House, respectively, held hearings on farmers' requests for an alternative non-H-2A guest worker program. None of these hearings focused on bills or concrete proposals, since the Gallegly-Pombo proposal was not yet available. Instead, the hearings typically featured farmers making three arguments, and worker, government, and academic representatives responding.

The three major grower arguments were:

1. That illegal aliens comprise a significant share of the current farm labor force. Growers testified that illegal aliens are 50 to 70 percent of some harvest crews, and they implied that this percentage is typical of the entire hired farm work force despite the legalization of over one million unauthorized workers in the SAW program in 1987-88 (The U.S. Department of Labor estimates that 25 percent of the labor force on U.S. crop farms was unauthorized in 1993-94.)

2. That new control measures under consideration in Congress—more border controls, more interior enforcement, and a more secure work authorization document—would prevent them from continuing to hire unauthorized workers who present fraudulent documents. Effective controls on hiring illegal aliens would leave them with a labor shortage, they asserted.

3. That the current H-2A program is too inflexible to provide them with foreign workers if labor shortages appear—the U.S. workers recruited for employers allegedly do not show up, work hard, or remain with the employer; growers must pay U.S. and H-2A workers the higher of three

wages—prevailing, minimum, or adverse effect wage rate—and provide housing at no charge to the U.S. and temporary foreign workers. In the words of one grower, the H-2A program is "too structured for a labor market that is relatively unstructured."

Worker representatives attacked these grower arguments by asserting that there is no shortage of workers, only a shortage of decent wages, benefits, and working conditions.

Second, worker advocates argued that employers prefer vulnerable foreign workers to U.S. workers. In North Carolina, for example, it was asserted that U.S. citizen-Puerto Rican workers were sent to employers where they would not have work for two weeks, and told that they would have to live at their own expense until the harvest began, while H-2A workers were sent to work immediately. It is no wonder, they assert, that U.S. workers under such circumstances abandoned these farm jobs, while H-2A workers stay with their employers as required by their visas.

Most government representatives opposed the growers proposal. The INS and DOL dislike the lack of control over entries under the growers' proposal, and even the USDA acknowledges that a free agent-attestation guest worker program may not provide workers to isolated areas most in need of migrant farm workers.

Academics generally argued that the U.S. farm labor market could adjust to the absence of immigrant workers—legal, illegal, or guest workers—with very little effects on the average American. Academics testified that:

First, it is unlikely that currently unauthorized workers will be removed quickly from the farm work force.

Second, even if the 20 to 30 percent of the current work force that is illegal were removed from the farm work force, U.S. consumers may not notice their removal in food costs because farm worker wages are, on average, only about 11 cents of a $1 produce item. Farmers receive about one-third of the retail price of most fruits and vegetables, and farm workers receive one-third of the farmer's price. This means, that for a $1 head of lettuce, farmers get an average $0.33, and farm workers $0.11.

Removing 20 to 30 percent of the farm labor force might raise farm wages. If done quickly, as at the end of the Bracero Program, farm wages might rise by 30 to 50 percent—the UFW was able to negotiate a 40 percent one-year wage increase in 1966 because farm wages had been held down by Braceros, and Braceros were no longer available. If farm wages rose 50 percent, from today's $4 to $6 range to $6 to $9 per hour, and if all of the wage increases were passed on to consumers, the head of lettuce would cost consumers $1.05, i.e., a doubling of farm wages leads to a five percent retail price increase.

Retail produce prices may fall rather than rise, as occurred when the end of the Bracero Program encouraged farmers and processors to change the way that tomatoes

were handled. In the tomato case, the end of immigrant labor caused production to rise, and retail prices to fall.

The tomato example illustrates that it is very hard to predict what will happen when the labor supply changes. Many growers in 1963 testified that the tomato industry had no choice but to follow its pickers to Mexico, shifting production there. Instead, the harvest was mechanized, and today almost five times more tomatoes are produced in California. Those closest to the adjustment issue may not have the clearest picture of likely adjustments.

Most of the adjustments to fewer and more expensive workers in agriculture occur on the DEMAND, not the supply side, of the labor market. In other words, in the face of immigration reforms, lasting adjustments are more likely to be found by accelerating labor-saving mechanization, or changing the way farm work is done, or letting production of the commodity shift overseas, not in launching new efforts to recruit U.S. workers, to build housing for migrant workers, or to provide government services to farm workers that raise their effective incomes.

The notion that most adjustments to fewer and more expensive farm workers reduce the demand for farm labor, not increase the supply, reflects experience in the U.S. and elsewhere. This is why, in most societies, development is associated with a smaller percentage of the work force producing food.

Growers and their supporters typically frame the argument in a manner that looks for SUPPLY adjustments. For example, if there are currently 100 workers employed and 30 are unauthorized, effective immigration controls would require the government to find 30 new workers.

The removal of unauthorized or guest workers from the farm work force rarely prompts U.S. workers to replace them. The more common response is for growers to demand fewer workers, often by mechanizing hand-harvest tasks.

Engineers point out that there are alternatives to hand work in agriculture, even to harvest raisin grapes, the crop often associated with recently arrived and illegal workers. One California grower planted twice the number of raisin vines per acre, cut the canes by hand to let the raisins dry on the vine, and then harvested the dried-on-the-vine raisins mechanically by shaking the raisins off the vines. Machines to eliminate most of the 50,000 four-to-eight week hand harvesters are available at a cost of $18,000 to $55,000 each.

In evaluating future agricultural guest worker proposals, three questions might be borne in mind:

First, are there any indications of labor shortages that are putting upward pressure on farm wages?

Second, if farm wages rise, how does the supply of labor respond, e.g., do rising wages encourage more workers to seek farm jobs, or current workers to work more hours?

Third, do rising wages set in motion technological, trade, or other changes that reduce the demand for farm workers?

The rationale for guest workers is that the labor market is not responding properly to market signals such as rising wages, or that government intervention is needed to prevent market adjustments that would have negative effects, such as rising food prices. If a new guest worker program begins before any of these adjustments can be observed, it will never be known how easily the farm labor market can adjust to changes in its labor supply.

Mid-1980s versus Mid-1990s

In the mid-1980s, despite opposition from the Reagan administration and the major sponsors of immigration reform legislation, farmers successfully included in the Simpson-Mazzoli legislation guest worker proposals.

In June 1984, Congress adopted the Panetta-Morrison amendment that would have established a free agent guest worker program for agriculture—what the New York Times termed one of the top ten political stories of 1984 (Leon Panetta, D-CA, who led the fight for the growers in the House, is President Clinton's chief of staff).[6] Then-senator Pete Wilson (R-CA) persuaded the Senate to approve a similar free agent program in 1985.

Mexico-Canada Guest Worker Program

Since 1974, Mexicans have been traveling to Canada to work seasonally in agriculture under a program that is very similar to the Bracero Program. Canadian farm employers—three-fourths in Ontario—get certified by their Department of Labor to have Mexican farm workers admitted, and then the Mexican Department of Labor recruits workers to travel to Canada. In the early 1990s, about 5000 Mexican workers were employed on Canadian farms each year, almost double the 2700 in 1988.

Under the program, Canadian employers offer Mexican workers contracts approved by both governments that, inter alia, guarantee wages of at least $C5 to $C6 per hour, at least 240 hours of work in six weeks, for seasonal earnings of up to $C2000, and free housing and either meals or cooking facilities. Mexican workers, two-thirds of whom are requested by name, pay about $C160 for a Mexican passport and Canadian visa.

When this program was described in October 1995, it was noted that almost 20 percent of the Mexican workers headed to Canada were from Tlaxcala, a Mexican state not noted for significant emigration. Indeed, some Mexican studies suggest that this guest worker program may be leading to a trickle of illegal

immigration—a 1988 survey found at least 13 workers who returned to Canada as illegal workers.

Notes

1. The Mexican government did not permit Braceros to be employed legally in Texas during the war years, 1942-47, because of past abuses and state discrimination against Mexicans. Many Mexicans entered Texas illegally to work on farms.

2. Despite explicit regulations prohibiting Braceros from being used to break strikes, DiGiorgio was able to use them for six weeks of the strike, until the federal government stopped their employment.

3. In some states, including Sonora, Braceros had to pick a certain amount of cotton locally before they were permitted to depart for the U.S. (Taylor, 1963, 43).

4. By the early 1960s, an estimated 85 percent of Braceros sent north had been in the U.S. before.

5. Secretary of Labor Wirtz interpreted the decision to terminate the Bracero Program as signifying congressional intent to reduce or eliminate the presence of temporary foreign workers in U.S. agriculture. Under December 19, 1964 DOL regulations, U.S. employers wishing to receive DOL certification to import H-2 workers had to attempt to recruit U.S. workers at a DOL-established Adverse Effect Wage Rate (AEWR), and to offer such workers free housing, round-trip transportation, and then receive e certification to employ H-2 workers for a maximum of 120 days, because "the only justification for bringing in labor is to meet the peak conditions the highly seasonal agricultural industry" (Congressional Research Service, 1980, p. 65).

6. John Norton, Undersecretary of Agriculture in the mid-1980s and a major lettuce grower, said that "Leon Panetta carried the ball for California on the Panetta-Morrison amendment... He did a superb job of trying to represent California's labor needs... he's been a real champion of the industry." California Farmer, June 21, 1986, 7.

FACTORS THAT INFLUENCE MIGRATION

Proposition 187 in California

Philip Martin

California voters on November 8, 1994 voted 59 to 41 percent to approve Proposition 187, the "Save Our State" Initiative. Proposition 187, if implemented, would create a state-run system to verify the legal status of all persons seeking public education, health care, and other public benefits. The only sections of Prop 187 currently in effect are those that make the manufacture, distribution, or use of false documents to obtain employment or public benefits a state felony.

Proposition 187 primarily creates a state-mandated screening system to prevent unauthorized persons from obtaining public services. In the words of the initiative—no person "shall receive any public social services to which he or she may otherwise be entitled until the legal status of that person has been verified."

A majority of voters in 50 of California's 58 counties supported Prop 187—the exceptions were eight San Francisco Bay Area counties. According to exit polls, 64 percent of whites, 57 percent of Asian-Americans, 56 percent of African-Americans, and 31 percent of Latinos voted in favor of Prop. 187. Some 78 percent of those voting in favor of Prop. 187 agreed that "it sends a message that needs to be sent" and 51 percent agreed that "it will force the federal government to face the issue." Some 40 percent of voters in one exit poll said that they voted primarily because Prop. 187 was on the ballot.

Of those voting against the measure, 60 percent agreed with the statement that it "doesn't solve the problem" and about 40 percent agreed that "it would throw children out of school" and that "it is racist/anti-Latino."

California's population is 57 percent white, 25 percent Latino, nine percent Asian-American, and seven percent African American. However, voters on November 8, 1994 were 75 to 80 percent white, eight to 10 percent Latino, four to five percent Asian-American, and 10 percent African-American.

Proposition 187 may mark the beginning of national efforts to reduce legal and illegal immigration, much as Proposition 13 in 1978 arguably laid the basis for the Reagan-era tax cuts of the early 1980s. On the other hand, Proposition 187 may be turn out to be a largely symbolic expression of frustration with illegal immigration, much as Proposition 63, which made English the state's "official language" in 1986, proved to be.

Provisions

Proposition 187 has five major sections. First, it bars illegal aliens from the state's public education systems from kindergarten through university, and requires public educational institutions to begin verifying the legal status of both students (effective January 1, 1995) and their parents (effective January 1, 1996).

California educational institutions today verify the residence but not the legal status of elementary school pupils and university students. There are no tuition charges for K-12 education. One of California's three higher education systems—the state university system—charges resident illegal aliens lower in-state tuition, while community colleges and UC charge them higher out-of state tuition. Almost 1 in 7 college and university students in the U.S. attends a public institution in CA.

Second, Proposition 187 requires all providers of publicly-paid, non-emergency health care services to verify the legal status of persons seeking services in order to be reimbursed by the state of CA. Persons seeking emergency care must also establish their legal status, but unauthorized persons must be provided emergency health services.

Third, Proposition 187 requires that all persons seeking cash assistance and other benefits verify their legal status before receiving benefits. Unauthorized aliens are generally not eligible for such benefits, so this provision establishes a state-run eligibility system to screen applicants for benefits.

Fourth, all service providers are required to report suspected illegal aliens to California's Attorney General and to the INS. This means that those enrolling children in school, or those determining eligibility for public benefits, are required to report persons they suspect of being unauthorized. State and local police must determine the legal status of persons arrested, and report unauthorized aliens.

Fifth, the making, distribution, and use of false documents to obtain public benefits or employment by concealing one's legal status is now a state felony, punishable by fines and prison terms. Prop 187 does not affect e.g., teenagers who buy or use false documents to obtain alcohol.

Proposition 187 is an initiative statute whose provisions remain state law unless disapproved by a two-thirds vote of the California Legislature or by another initiative. Sections of Prop 187 can be implemented individually. On November 9, 1994, Governor Wilson ordered that state-reimbursed health services for prenatal care be stopped as soon as possible, and that no more unauthorized aliens be enrolled in state-reimbursed long-term health care programs (nursing home care).

Campaign

Proposition 187 initiative began with a huge lead in opinion polls—it had a 37-point lead in July, 1994, and led among likely voters by 62 to 29 percent in mid-September, 1994. However, by early November, polls indicated that as many likely voters opposed as supported SOS. Most politicians and opinion leaders argued that voters should reject Proposition 187 because it was too blunt an instrument to deal with the complex issue of illegal immigration. No major newspaper endorsed Proposition 187.

In the week before the election, Governor Wilson, who was re-elected with 55 percent of the vote, asserted that if Proposition 187 became law, he would require state and local government employees to report suspected illegal aliens as required by the initiative. California Attorney General Dan Lungren, who was also re-elected, promised to develop emergency regulations to implement the initiative immediately, but noted that there was no penalty for persons who do not report suspected illegal aliens.

Wilson's campaign bought the only pro-Proposition 187 TV ads that were aired, while the anti-187 campaign used contributions from doctors and teachers to run anti-Proposition 187 TV ads. Democratic gubernatorial challenger Kathleen Brown ran out of money for TV ads at the end of her campaign, and toured high school and college campuses, urging students to work to defeat Proposition 187.

President Clinton argued against Proposition 187. According to Clinton, "it is not wrong for you [Californians] to want to reduce illegal immigration. And it is not wrong for you to say it is a national responsibility." Clinton said that "the federal government should do more to help to stop illegal immigration and to help California bear the costs of the illegal immigrants who are there," but urged California voters to reject Proposition 187 and allow the federal government to "keep working on what we're doing—stiffening the border patrol, stiffening the sanctions on

employers who knowingly hire illegal immigrants, stiffening our ability to get illegal immigrants out of the work force, increasing our ability to deport people who have committed crimes who are illegal immigrants."

The campaign's final days were marked by large numbers of Hispanic students walking out of high school to protest Proposition 187, and by charges of hypocrisy between U.S. Senate candidates Feinstein and Huffington. Both took tough stands against illegal immigration, and both charged that the other employed an illegal alien maid. Feinstein hired an illegal housekeeper in the early 1980s—before it was unlawful for a U.S. employer to knowingly hire illegal alien workers—and Huffington hired an illegal alien nanny in the late 1980s and early 1990s, when such hiring was unlawful. Feinstein was narrowly re-elected.

The Mexican government actively opposed Proposition 187. In his final state-of-the-nation address, former Mexican President Carlos Salinas de Gortari asserted that "Mexico affirms rejection of this xenophobic campaign, and will continue to act in defense of the labor and human rights of our migrant workers." Ernesto Zedillo, who became Mexico's President on December 1, 1994 asserted during a November, 1994 trip to Washington, DC that Mexico "cannot object to legitimate enforcement of U.S. laws," but Mexico objects to "enforcement [that] might lead to deprivation or violation of basic human rights... [including] education and health care."

Status

On November 20, 1995, a federal judge, in a 72-page opinion (League of United Latin American Citizens v. Wilson, Case No. CV 94-7569 MRP, declared most parts of Prop. 187 unconstitutional. The judge held that "Proposition 187's verification, notification and cooperation/reporting requirements directly regulate immigration [which only the federal government can do] by creating a comprehensive scheme to detect and report the presence and effect the removal of illegal aliens."

The key distinction in most of the ruling is the source of funds for programs. If a program is funded with both federal and state funds, the judge ruled that California could not unilaterally make illegal aliens ineligible for benefits. But if the program is funded with state funds only, then California can make illegal aliens ineligible for benefits. Only in K-12 education is the source of funds irrelevant—in this case, a 1982 U.S. Supreme Court decision requires states to educate illegal alien children. The judge ruled, however, that under federal law California can deny entry and in-state tuition status to illegal aliens seeking entry to colleges and universities.

Attorneys representing California argued that the state has a right and duty to conserve scarce state funds, and to spend them as voters wish. The federal

judge, by contrast, emphasized that only the federal government has the power to regulate immigration.

The California State Attorney General on January 31, 1996 asked the court's permission to exclude illegal aliens from 23 state programs, ranging from state-funded abortion to child abuse prevention programs—wholly state-funded programs.

Reactions

Proposition 187 was based on the theory that changes in immigrant policy can affect immigration flows. According to Governor Wilson, denying public services to unauthorized aliens would discourage them from coming to the U.S., and encourage some who are here to leave.

In March 1996, the U.S. House of Representatives approved, on a 257-163 vote with Speaker Gingrich's support, a so-called "Proposition 187 or Gallegly" amendment to immigration reform legislation that would permit states to deny public education to illegal alien children, and to prohibit states from offering federally financed welfare benefits to illegal aliens. Many experts believe that, if Congress approves the denial of free public education to unauthorized children, the U.S. Supreme Court will reverse the 5 to 4 Plyler vs Doe decision in 1982 that found unconstitutional a 1975 Texas law that kept unauthorized children out of school. In the Plyler decision, the Supreme Court acknowledged that education was not a "fundamental right," but the majority decision emphasized that Texas provided no evidence "suggesting that illegal entrants impose any significant burden on the state's economy."

Bob Dole supported the Gallegly amendment; President Clinton opposed it. There are an estimated 700,000 illegal alien children in K-12 U.S. schools, including 355,000 in California

There was an attempt to put a Save Our State II initiative on the November 1996 ballot, but it failed to secure enough signatures. Save Our State II would have required all applicants for welfare payments or other government benefits in California to present state-issued identification cards proving their U.S. citizenship or legal residency, all persons born in California to be fingerprinted at birth, and all birth certificates to contain information regarding the residency status of the baby's mother.

FACTORS THAT INFLUENCE MIGRATION

Mexican Migration Project Data

Katharine Donato

In this section, we present findings from an analysis of data from the Mexican Migration Project (MMP). Its purpose is to examine the extent to which Mexi can men and women migrate legally and illegally to the United States, trends in the chances of migrating over time, and whether and how migration patterns differ by community of origin. The MMP data were collected in the 1980s and early 1990s from about 200 households in each of 39 communities in western central Mexico, a region of Mexico surrounding the city of Guadalajara from which most U.S. migrants were born (MMP, 1995). The communities range in size from 1000-person ranchos to a section of Guadalajara, which had a 1990 population of 2.9 million (see Table 1).

In each of the 39 communities, households were randomly selected and interviews were conducted in December-January when sojourner U.S. migrants often return to Mexico. Individual migration histories were compiled for all members of the household, including those absent when the interview was conducted.

Interviewers spoke with household heads and obtained information on all children, whether they were present or not, and if absent, whether they were in Mexico or the United States (Massey and Espinosa, 1995, 4). For the household heads, migration histories were compiled for each year after age 15, and they included questions such as did the person migrate to the United States and if so,

with or without documents. In addition, interviewers collected data from about 20 migration households who had moved to the U.S. in the summer following data collection in Mexico.

Migrating on a First and Subsequent U.S. Trip

To examine the chances of making a first U.S. trip, the key variables are birth dates and when and how each household member took a first trip to the United States by the time of the interview. For each year of life, a household member had three possible choices: (1) not to make a trip, coded as zero; (2) to make an unauthorized trip (either w/o docs or with tourist visas, border crossing cards, or borrowed/false docs, who also had U.S. work experience), coded as one; or (3) to migrate legally, coded two. Once a person migrated, he or she was excluded from subsequent analysis.

Individual life-histories were used to estimate age-period models of migration. For men and women, two types of probabilities are estimated:

(1) the probability that a man/woman aged 20-24 would migrate, legally or illegally, to the United States for the first time in a given year, and

(2) the cumulative probability that men/women by age 40 would have made a first legal or illegal trip to the United States.[1]

We then extended these models to measure recurrent migration, and therefore, estimated two sets of probabilities:

(1) the probability that a young man would migrate, legally or illegally, on a subsequent trip (after making a first trip), and

(2) the cumulative probability that men by age 40 would migrate on a second legal or illegal U.S. trip.[2]

For example, in Community 2, a large metro area in the state of Guanajuato, the chance that a young man aged 20-24 would migrate illegally to the United States was just 1 percent in 1994. Based on the model and year-by-year migration probabilities for all men in the sample, we would expect about 16 percent of men to migrate to the U.S. at least once illegally by age 40.

To better understand trends over time, consider a typical community, say community 11, which in 1990 was a small urban area with a population of 20,000. Table 2 shows that 12 percent of men aged 20-24 in this community took a first illegal trip in 1980. Ten years later, despite high rates of legal migration associated with IRCA's amnesty program, 11 percent of the young men made a first unauthorized trip. However, in 1991, the chance of making an illegal first trip dropped to 5 percent, then rose to 7 percent in 1994, meaning that 7 of 100 young men in community 11 made a first illegal trip to the United States in 1994.

Probabilities for communities 3 and 10, which are much smaller and more typical of the villages that depend on emigration and remittances to supplement earnings from a mostly agricultural economy, illustrate similar patterns. In general, young men were more likely to make a first illegal than legal U.S. trip until 1986. In 1986, the chance of making a first illegal trip from community 10 was 45 percent, twice as high as making a first legal trip. In community 3, the chance of making an unauthorized trip was 38 percent, more than 10 times higher than making a legal trip.

By 1987, the pattern had changed. In community 3, young men still faced higher chances of migrating illegally than legally, but the difference between the two narrowed considerably after 1986. For men in community 10, however, the pattern reversed—beginning in 1987, the chance that a young man would migrate legally was higher than migrating illegally. In 1992, 60 of 100 young men in community 10 made a first authorized trip, representing the highest migration probability recorded since 1980.

The second panel of Table 2 presents cumulative probabilities which answer the question, what is the probability that a young man would have taken at least

one unauthorized or legal trip to the United States by age 40? The probabilities for each community are based on the rates of out migration that were estimated for each community between 1940 and 1992. Young men enter the pool of potential migrants at birth, and leave at age 39 or by death. The pool of those who could migrate—the denominator—is all men in the community under age 40 who have so far not migrated legally or illegally.

Once again, beginning with community 2, men by age 40 had a 29 percent chance of migrating illegally on a first trip in 1980, or about one in three men under 40 in this section of Guadalarja were predicted to have made at least one illegal trip to the U.S. by 1980. By the mid 1980s, the chance that a man would make at least one illegal trip rose to 36 percent but then fell, dropping to 20 percent and in 1988 to just 8 percent. The decline continued through 1992, when the lifetime chance of making a first unauthorized trip was just 5 percent. However, two years later, it had risen to 16 percent.

So far, our results suggest three key findings. First, from some communities, virtually all young men will make an initial U.S. trip by age 40. Second, the chances of migrating illegally and legally vary considerably by origin community—they are lower than in larger metropolitan areas than in smaller rural communities. Third, despite declines immediately after 1986, the probability of making an initial unauthorized U.S. trip by age 40 began to rise again by the 1990s, based on a model that uses migration experience through 1992.

Table 3 presents the same probabilities of migration calculated for women in the four communities. Like those for men, they reveal that: (1) by age 40, most women will migrate to the United States on a first trip; and (2) the incentives to migrate have changed since 1980. However, despite the similarities, year-by-year probabilities show that shifts in the chances of migrating legally and illegally were more gradual than those for men. For example, declines in the chances that a woman would migrate illegally occurred in the 1990s rather than immediately after 1986.

Finally, the probabilities presented in Table 4 suggest that more recent repeat trips to the United States were made with legal documents rather than without them. In communities 2, 11, and 10, the lifetime chance of making a second trip (after making a first) with legal documents was much higher than making an illegal trip in the mid 1990s. Before 1987, however, the chance of making a second unauthorized trip was much higher than migrating legally.

Community Similarities and Differences

To better understand migration trends over a longer period of time for all 39 communities, we estimated the probabilities of migration separately for each year beginning in 1943. From these probabilities (see Appendices 1-3), we derive

*Community 2 represents communities 2 and 24.

Figures 1-15. Figures 1-5 illustrates trends in the chances that a male household head migrates on a first U.S. trip, Figures 6-10 document shifts in the chances that a woman migrates on a first U.S. trip, and Figures 11-15 describe trends in the chances that a male household head makes a second U.S. trip. In each set of figures, the first figure summarizes the probabilities of migrating across all 39 communities in 1943-94, and the next four figures describe the probabilities for communities 2, 11, 3 and 10 in 1971-94.

On the whole, the figures reveal the same difference that we observed earlier between the predicted and cumulative probabilities. The predicted chances that young men migrate on a first illegal or legal trip at age 20-24 was quite low throughout the period, but magnified over 40 years, the chances of migrating were considerably higher.

Figure 1 illustrates how, in the beginning of the Bracero period, the chance that young men would migrate on a first U.S. trip with documents was higher than the probability of migrating illegally. In 1947, young men were more likely to migrate illegally but, after Operation Wetback in 1954, the probabilities reversed again, and legal migration became the norm until the end of the Bracero Program.

After 1964, however, the cumulative probability that young men migrated legally trended downward, while the cumulative probability of a first illegal trip moved up, peaking at 80 percent in these emigration communities in 1983. Since then, the lifetime probability that a young man would migrate on a first legal trip to the United States by age 40 has fluctuated, with legal and illegal probabilities following similar year-by-year patterns, reaching an all-time low of approximately 20 percent in 1990, and then doubling to at least 40 percent by 1994.

These trends are consistent with evidence that stepped up enforcement and the increased legalization of Braceros in the mid-1950s helped lower the chances of illegal first-time entry. As the number of Braceros was reduced in the late 1950s, and reduced to zero after 1964, the chances of illegal entry grew. This upward pattern continued until the mid 1980s, when IRCA produced both a legalization program and a series of incentives explicitly designed to reduce illegal entry to the United States. As a consequence, the probability of first-time illegal migration dramatically declined in the late 1980s, intersected with that for legal migration, and in recent years the chances of legal and illegal migration converged.

Figures 2 through 5 illustrate how the pressures to migrate have changed over time in the four typical communities. Unlike Figure 1 that described the average probabilities across all 39 communities, trends in Figures 2 through 5 document striking differences among the villages in the chances of migrating on a first U.S. trip. For example, the figures show clearly that, in community 2, a less established migrant sending community, the chance of illegal migration was much lower, and less symmetric, than in other communities. In addition, although the chance of

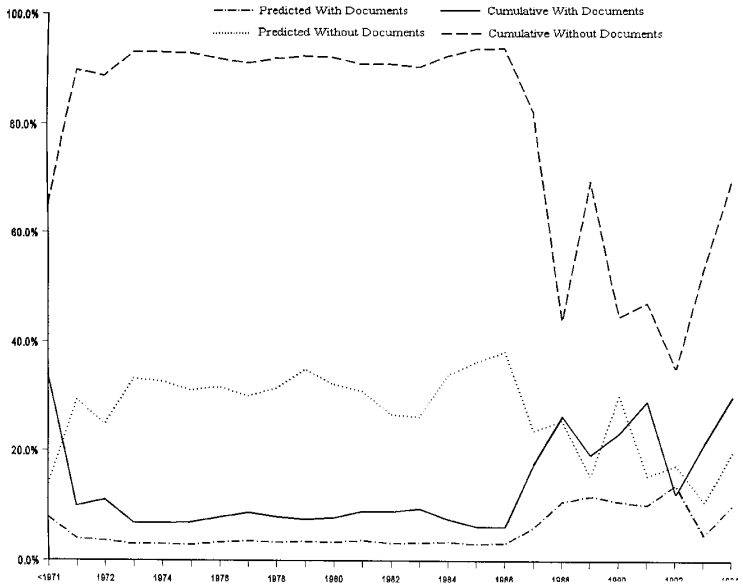

Figure 4. Chances That a Male Household Head Migrates On a First U.S. Trip, for Community 3, 1971–94

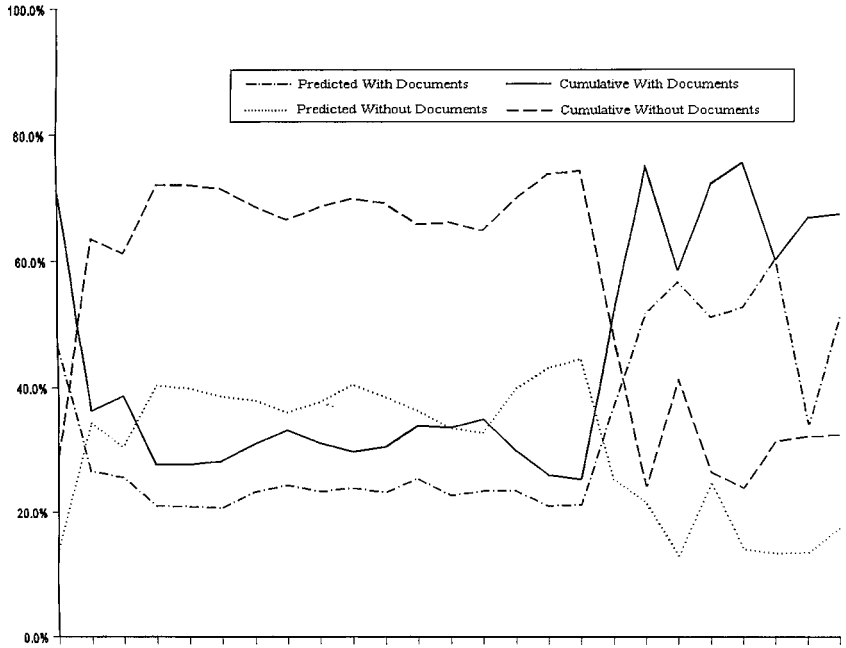

Figure 5. Chances That a Male Household Head Migrates On a First U.S. Trip, for Community 10, 1971–94

making a first illegal trip was higher than a first legal trip from 1971 to 1987 for all communities, since then, differences across communities have emerged. Community 2 is noteworthy in this regard because young men remain more likely to migrate illegally than legally since 1986.

In communities 3 and 10, the most established migrant sending origins from which virtually everyone migrates on a first trip with or without documents, overall trends reveal remarkably high levels of migration and almost perfect symmetry between the two types of cumulative probabilities (see Figures 4 and 5). In 1971, from community 3, the lifetime chance of migrating illegally was close to 90 percent, whereas the chance of illegal migration dropped to roughly 10 percent. In that same year, the cumulative chance of migrating on a first U.S. trip from community 10 was 65 percent for men without documents and 35 percent for those making legal trips.

The chances of migrating continued at the same high levels through 1986, but with an important distinction—migrating legally replaced migrating illegally in these two villages. During the post-IRCA period, the chance of making a legal trip by age 40 grew to a high of 40 percent in community 3, and 80 percent in community 10. In both communities, upward or downward shifts in the chances

of legal and illegal migration essentially mirror each other—a drop in the chance of illegal migration occurred in the same year that the chance of legal migration increased. Despite the shifts, however, the combined chances of migration suggest that virtually everyone will migrate on a first trip by age 40.

Community 10 illustrates Massey et al.'s (1994) view of how migration has become a self-feeding process. Of the 39 communities in the data set, this community has the longest history of U.S. migration. Many residents were legalized in 1987-88, so that the probability of migrating on a first legal trip rose in 1988 and surpassed the chance of making a first unauthorized trip. Later, in the 1990s, with documents themselves, these migrants sponsored the legal migration of their dependents, thus facilitating very high levels of legal migration from this community.

In contrast to the patterns for men, women's chances of migrating on a first legal trip are higher than for a first unauthorized trip throughout the 1943-94 period (see Figure 6). Dramatic increases occurred in two periods. The mid 1960s witnessed the legalization of many Braceros, who in turn sponsored their immediate family

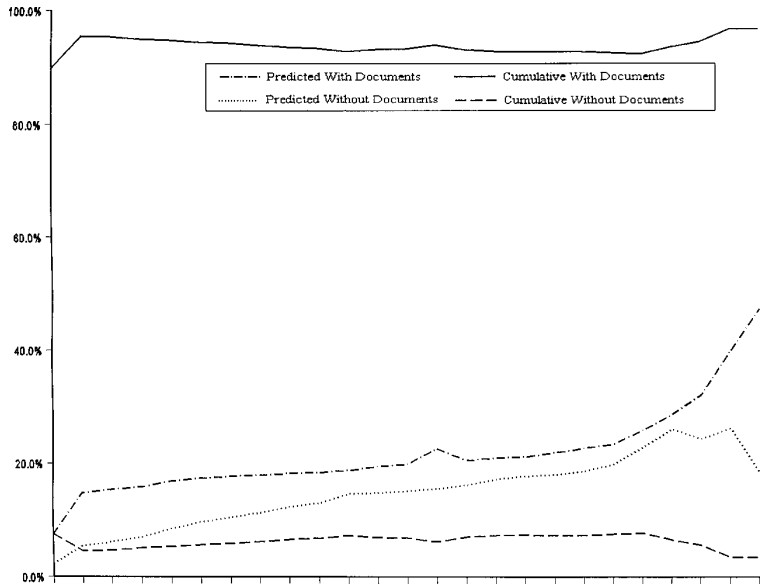

Figure 10. Chances That a Woman Migrates on a First U.S. Trip, for Community 10, 1971–94

members (many of them women) for purposes of family unification (Donato, 1993). In the early 1990s, there was a second peak in a woman's chance to migrate legally as many began to enter as relatives of IRCA's amnesty recipients.

Interestingly, however, Figures 7-10 show that trends in individual communities may differ from Figure 6. For example, community 3 was unusual because here a woman's chance of migrating illegally was higher than migrating legally until 199, when legal migration became the norm. In community 10, the gap in the lifetime chances of legal versus illegal migration was much larger than that observed for all 39 communities.

Finally, Figures 11-15 reveal trends in the chances that men migrate on a second U.S. trip. Across all 39 communities, the cumulative probability of migrating legally was higher than illegal migration during the 1942-64 Bracero period. The crossover year was 1963, when the chances of migrating illegally exceeded those for legal migration. This state of affairs continued until the late 1980s, when the chances of making a second legal trip were higher than making illegal trips. By the early 1990s, however, the two probabilities converged so that roughly 50 percent of men migrated on an illegal or legal second trip.

Assessment

These data suggest that the majority of men and women will leave traditional emigration communities west central Mexico on a first U.S. trip by age 40, and that most men will make a subsequent trip. On a year-by-year basis, the major difference was whether Mexicans made their first trips legally or illegally, not whether or not they migrate. Legal status differences were also related to community of origin. From traditional emigration communities, prior high levels of illegal migration have fed on themselves, changing the legal status of newly arriving Mexican migrants without shifting the overall pressures to migrate over the long term. In fact, the present analysis reveals that the chance of migrating on a first trip has begun to rise in the 1990s.

Together with findings from prior community studies, these data suggest that the pressures to migrate are now as high as ever. Although the legalization program appears related to a rapid rise in probabilities of legal migration, it is clear that the overall pressures to migrate in many communities in west central Mexico remain is strong and may be on the rise. So the question is how to get over the current migration peak or hump.[3]

Examination of migration trends suggests that stepped up enforcement and a legalization program for Braceros combined to lower the chances of illegal migration in the mid-1950s. By the early 1990s, a similar two-pronged control policy existed in the United States. Although the legalization program implemented as part of IRCA and several stepped-up border enforcement programs, especially in San Diego and El Paso, also lowered the chances of illegal first-time migration from Mexico, the pressures to migrate have remained high.

Therefore, our re-analysis of these data suggests that recent migration from communities with long trajectories of migration has become a self-feeding process. After 1986, with amnesty and the ability to sponsor their relatives, many more migrants have been entering legally. But at the same time that the incentives to migrate legally and illegally have changed, high levels of migration prevail.

Notes

1. Note that both probabilities derive from weighted models to correct for differences between the U.S. and Mexican samples. Within Mexico, weights are the number of households in the community divided by the number of households in the sample. Within the United States, weights are the number of out migrant households from each community living in the United States divided by the number of households in each community surveyed in the United States. By pooling and weighing the U.S. and Mexican samples, these data provide a representative profile of the total binational population of all communities in the data set.

2. Unfortunately, data are not yet available to estimate probabilities of recurrent migration for women.

3. This conclusion contrasts with that made by Reyes (1997), who analyzed the MMP data and reported that approximately 50 percent of Mexican migrants return to Mexico. Although many do return home, her figure derives from an analysis that is biased in favor of high emigration rates. By including all MMP observations, of which many refer to the 1942-64 period when Mexican workers were recruited by the U.S. government to work in agriculture and then return home, her estimate of return migration is likely to overestimate the extent to which recent migrants (in the last 10-15 years or so) return to Mexico

Technical Appendix: MMP Analysis

The MMP data permit us to separately distinguish between the chances of making an initial (first) or subsequent (two or more) trip to the United States. Together these events determine the overall flow of legal and illegal migrants across the border (see Donato et al., 1992). In this report, we examined the chances that male household heads and women migrate on an initial U.S. trip, and for men, the chances that they migrate on a subsequent trip.

For the analysis, we drew on two basic sources of information: the birth date and the date of the first trip to the United States (compiled for all household members) and the history of border crossing (gathered from household heads). Given each subject's date of birth and year of first trip, we first constructed separate year-by-year life histories up to the date of the first U.S. trip for both men and women. That is, we built discrete-time person-year files that followed each subject from birth to the date of the survey or to the first U.S. trip, whichever came first. For the recurrent trip analysis, we built a similar discrete-time person year file but constructed it from year-by-year files that began with the year migrants returned from their first trip up to the year of their next trip.

Because the outcome measure was trichotomous (migrated illegally, legally, or did not migrate), we used multinomial logistic regression to estimate the chance of migrating with and without legal papers versus not migrating at all (the reference category) (Hosmer and Lemeshow, 1989). The multinomial logit equation is given below:

$$g_j(x) = \ln \quad \frac{P(Y = j \mid x)}{P(Y = 0 \mid x)}$$

$$= \beta_{j0} + \beta_{j1}x_1 + \beta_{j2}x_2 + \beta_{j3}x_3$$

where j represents legal status of migration on a first (or subsequent) trip and 0 indicates no migration, and where P (Y = j| x) is the probability of migration with legal status j given a set of characteristics represented by the vector x. The effects of the explanatory variables in time t on the log-odds (g_j (x)) of migrating with legal status j in t + 1 are; age given by β_{j1}, period given by β_{j2}, and community given by β_{j3}. Note that period and age are time varying, whereas community is a fixed variable.

We began by estimating age-period models and age-period-community models (see Technical Appendix Tables 1A-3B). From them, we calculated the conditional chances that male household heads (or women) of a given age migrate, legally or illegally, on an initial U.S. trip using the equation below:

$$P(Y = j \mid x) = \frac{e^{g_j(x)}}{\sum_{k-0}^{2} e^{g_k(x)}}$$

where $\beta_0 = 0$ and hence $g_0(x) = 0$.

Using these probabilities as a baseline, we built life tables that produced the cumulative chances that men by age 40 would make a legal, illegal trip, or not migrate, in a certain year (Shyrock et al., 1976). Technical Appendix Table 5 depicts the lifetime migration experience in community 10 in 1994 by age, assuming the probabilities of Mexican out-migration that prevailed up to 1994. These figures show what would happen if a male household head born into this community were to go through life subject to the probabilities of out-migration prevailing in different years. The hypothetical probabilities begin with the assumption that at birth (age interval$_{x=0}$), the chance of not migrating, P(NM), equals 1 and the probabilities of migrating legally, P(ML), or illegally, P(MIL) equal 0.

At age interval ($_{x+1}$),

(1) the chance of not migrating is

$P(NM)_{x+1} = P(NM)_0 - [P(NM)_0 * (P\ (Y = \text{legal} \mid x \text{ given age} \leq 14) + P(Y = \text{illegal} \mid x \text{ given age} \leq 14)]$;

(2) the chance of migrating legally is

$P(ML)_{x+1} = [P(ML)_0 + (P(NM)_0 * P\ (Y = \text{legal} \mid x \text{ given age} \leq 14)]$; and

(3) the chance of migrating illegally is

$P(MIL)_{x+1} = [P(MIL)_0 + (P(NM)_0 * P\ (Y = \text{illegal} \mid x \text{ given age} \leq 14)]$.

Factors that Influence Migration

Coyotes and Alien Smuggling

Gustavo López Castro

Coyotes or polleros or pateros are persons who, for a fee, assist individuals wishing to enter the U.S. without legal authorization to do so. There have always been coyotes along the Mexico-U.S. border, but their activities became significant only after 1964, when the Bracero Program ended.

The number and range of services provided by coyotes have expanded. We surveyed 6 coyotes in Guanajuato, 2 in Michoacán, and 3 in Tijuana, as well as 3 INS investigators dealing with alien smuggling in California, and one 1 in El Paso. We also interviewed migrants seeking unauthorized entry into the U.S.

Since 1983, we found that most migrants attempting unauthorized entry into the U.S. used coyotes, although even in 1996, there were about one in four migrants who attempted to cross the border with the help of only friends or relatives or on their own.[1] We distinguish between three major types of coyotes: local agents, local and border smugglers, and border-only smuggling businesses, each with a menu of prices and services. The type of coyote used depends on migrant access to networks of friends and family—migrants without access to networks are most likely to arrive at the border by bus, and find a border-area business smuggler to help them to attempt entry into the U.S.

Table 1
Migrant Use of Coyotes

Type of Coyote	Migrants—No Network	Migrants—with Network
Local	9%	16%
Local and Border-Informal	18%	40%
Border-Business	53%	17%
No coyote	20%	27%

Source: questionnaires from the "International Migration in the Bajío project, CER/ColMich

A local coyote normally operates with at most two helpers from the same town or region, and specializes in telling potential migrants who to contact at the border to cross, and where to go once in the U.S. Some migrants go with family members or friends to the border, and make contact with a coyote from their town or region; such a local and border coyote may guide migrants across, have them picked up on the other side, and transport and deliver them to their destination. Such local-border coyotes often involve five to ten people and work with migrants from a particular town or area; many are loosely-structured groups.

The Bracero Program offered legal entry options and reduced coyote activities, but coyotes offered a means of entry for workers with no U.S. job contacts and thus little possibility of entering legally. In the late 1960s, when an offer of employment from a U.S. employer could be used to secure a green card and permanent residence, some workers used coyotes to find U.S. employers who would sponsor them. However, some of the workers who were eligible for green cards never completed the process, and instead continued to migrate seasonally and illegally to the U.S.

Local-Interior Coyotes

In Michoacán and Guanajuato, "everyone knows" where to find coyotes. These coyotes have one or two assistants (usually family members) to help them to organize groups of 5 or 6 migrants, take them to the border, help them cross into the United States, and then transport them to their final destination, which is often the where the coyotes themselves are going. The coyotes may then work in the U.S. for several months before returning to their hometown to organize another group of migrants. Their level of operational sophistication is minimal, and they normally use the same method to smuggle people across the border: crossing the Rio Bravo (in the case of

people from the north of Guanajuato state), or across the mountains of Tijuana and the Arizona desert (in the case of people from Michoacán state).

Once in the U.S., these coyotes use public transportation, including trains, buses and planes. Their failure rate is high—some report four attempts before successful entry, versus a claimed one attempt and your in by border business coyotes—but their commitment to the group means that they make as many attempts as necessary until they succeed in getting across. Paradoxically, when the local coyote himself is captured, he is rarely processed as a smuggler, because he appears to be just another migrant. Those with him are not inclined to denounce him as a smuggler, since they are acquaintances and friends; local coyotes are often considered paisanos or countrymen.[2]

Until the INS launched the IDENT and ENCATS systems in 1994, local coyotes had certain advantages over other coyotes because of their relationship with the people they tried to take across. Things have started to change, however, because at some border crossing points all undocumented workers captured are fingerprinted and photographed, enabling INS to detect local coyotes because of their more frequent apprehensions.

Although the fees charged by the local coyotes are generally lower than those of the other types of coyotes, the new INS identification systems have increased their risks and raised their fees Price differences have narrowed, and made price a less important factor in which type of coyote to use to enter the U.S.

Safety is one of the major reasons to use the services of a local coyote; migrants assume that they will have fewer physical risks if they go with someone they know from their area, someone whose family resides in the region, and someone who can bring news back to the town. This means that the prestige of the local coyote depends not so much on his rate of success in getting people across the border in as few attempts as possible, but upon the safety of the people who travel under his guidance and responsibility.

Economic factors also come into play. It is by not unusual for the family that stays behind to pay the coyote for his services once they are notified that their family member has arrived safely at his/her destination. In this situation, both the reputation and social position of the coyote are important; these will be determining factors in terms of the number of clients that he will be able to attract in the future.

Some local coyotes are part-time operators, taking people across the border only occasionally, or restricting their activities to friends and relatives. Some of these occasional coyotes have legal permission to enter the U.S., so they do not cross the border with migrants. Instead, they travel to the border with the migrants, and help to find a smuggler who will guide the migrants across, and then wait for the migrants inside the U.S. These occasional coyotes do not play a substantive role in the migratory flow.

Local and Border Coyotes

Some coyotes originally from the migrants' area of origin live in border areas, and get referrals from local coyotes or friends and family of past migrants. In many cases, migrants seek border area coyotes using a telephone number, an alias, or the name of a specific restaurant or hotel. With such a border contact, and someone who will take responsibility for the person once they make it into the U.S., migrants from Michoacán, Guanajuato, Zacatecas and Jalisco set out for the U.S.

Local and border coyotes set up loosely-structured groups characterized by a low level of technological sophistication. Most have two or three vehicles (usually vans) and use hotels as "safe rooms." They rarely use cellular telephones, citizen band radios or "beepers," and usually cross the border over the mountains, through ravines or by swimming and wading across the river; they rely on evading the INS rather than understanding its activities and attempting to outwit INS with decoys etc.

Membership in these groups is flexible. There is a leader, but the group is only brought together when there are migrants to be smuggled. Furthermore, the leader generally calls only those members whom he considers ideal for the job, thus minimizing losses and guaranteeing the continuity of his services.

Border Business Coyotes

Business coyotes have a long history in the border area, but smuggling migrants into the U.S. has evolved from a supplementary business to a full-time occupation. However, as the number of Mexicans entering the U.S. increased, and as U.S. employers sent their supervisors to the border area to recruit workers, some coyotes began to specialize in the movement of workers across the border.

Business coyotes developed after the Bracero Program ended in 1964. Some were unauthorized workers who had experience crossing the border, while others developed relatively sophisticated organizations that could recruit migrants as they arrived in the border area and provide a variety of services to them.

All business coyotes have three major elements; recruiters, guides, and U.S. agents or delivery persons. The recruiters linger around the bus and train stations—every day, 125 buses arrive from the interior of Mexico in Tijuana, and two trains arrive in Mexicali—or hotels that provide shelter to the migrants, or hang out in the bars and restaurants frequented by migrants, and make deals with potential migrants. As smuggling has evolved, there has been a shift from the "cash-in-advance" payment system and to the "payment-on-delivery" system—when the migrant reaches his U.S. destination, the migrant tells a family member or friend within the United States to pay the coyote.

The process of the crossing is straightforward: wait until dark, get the group together at a hotel or some other safe place, lead it to the border, cross through

some gap or hole or tunnel under the fence, or jump over the fence. The coyote then guides the group over the countryside on foot, walking, running, and hiding, until it arrives at a prearranged place where a delivery person with a vehicle is waiting to pick up the migrants and take them to a U.S. destination. Once the pollos have been dropped off, payment is made, and the coyote returns to Mexico to share the proceeds with his confederates. There are many variations; the distance to be walked is variable, depending on whether the vehicle meets the migrants in a rural or urban area, and affects the price paid by the migrant—more walking means lower prices.

Migrants do not need to use a coyote to attempt such entries, and some do not. Some know the border area so well that they use public transportation inside the U.S., such as the suburban trolleys in San Diego and then Amtrack to reach Los Angeles, or they take planes away from San Diego, El Paso or Laredo.

Smuggling women is more complicated. Business coyotes began to add women to their organizations, and to offer women and children one contact person from recruitment to guide to delivery. In some cases, the wife of the coyote helps to negotiate the agreement—virtually all are verbal—and then travels with family members to the border to watch the guide take women across. The coyote's wife remains with the family members until the women reached their destination in the U.S. as a form of security and a guarantee of delivery.

Most migrants attempt to elude the border patrol. But stepped up border controls and more women migrants have led more migrants to attempt to enter the U.S. using false documents. Especially during peak traffic periods, inspectors reportedly spend more time looking at the document than the person, so that it is relatively easy to borrow genuine documents and cross, a method preferred by many women. Some coyotes obtain green cards (known as "micas") and distribute them to migrants, taking into consideration physical similarity and ensuring that the migrant using them is older than the person shown on the card. Many coyotes also offer migrants Social Security cards and identification cards like those issued by the Department of Motor Vehicles. In some cases, valid Mexican passports with temporary U.S. visas are used. Children and babies are simpler to smuggle with false documents, because they typically do not require identification or photographs. In some cases, U.S. birth certificates can be used to enter the U.S. at border entry ports until children are 18.

False documents are used to attempt to enter the U.S. on foot or in autos, with the on-foot method preferred because of the risk that the vehicle will be confiscated, and the migrants' fellow passengers accused of smuggling. In most cases, coyotes send migrants, one at a time, and separated by 50 or 100 other crossers, to the port of entry. Once inside the U.S., the migrants report to a telephone booth or some other easily visible spot for further instructions. Walking through the port of

entry is one of the simplest and most expensive smuggling methods, costing as much as $800. Fewer coyotes attempt to conceal migrants inside vehicles, inside cargo containers, or in cars with double trunks; these methods often lead to tragedies, and are used less and less frequently.

Coyotes who have been in business since the 1970s report that there was relatively little demand for their services in the 1970s, because there were too many coyotes for the number of migrants who wanted to be smuggled—it was also easy to enter the U.S. without the help of a smuggler. Most migrants who turned to coyotes in the 1970s had special needs—women, children, the elderly, Central Americans, Asians. IRCA stimulated interest in coming to the U.S., and the possibility of obtaining a green card via the legalization programs led to a huge increase in the demand for coyote services, especially for the service of getting from the border area further inside the U.S. Smuggling people into the U.S., and moving them around within the U.S., proved to be enormously profitable, and made previous training and investments in safe houses and vehicles pay off.

After 1994, the coyote business changed once again. Business coyotes with a network of safe houses and vehicles have an advantage in evading stepped up border controls, and they have been able to charge migrants premium prices of $500 to $1500 because of their superior ability to smuggle them into the U.S.

Business coyotes remain centered in the border area, but they tend to recruit only the most profitable migrants, such as Central Americans and Asians. The smuggling system resembles a series of semi- autonomous links in a chain which extends from Chiapas to Chihuahua, in which the agents decide which transportation systems to use, which links to follow, and when it is most advantageous to "sell" their human cargo to the next agent. A large number of people participate as service providers, and none of them are surprised when 20 Salvadorans or 5 Chinese suddenly show up on their doorstep to eat or to spend the night. The principal objective is to get these (doubly undocumented) migrants into the United States; Central Americans and Asians are especially highly-valued since they pay the most to be smuggled into the U.S.

Conclusions

It is best to think of coyotes as business operators who are breaking both Mexican and U.S. law. Within Mexico, coyotes are considered somewhat shady characters, but they are perceived to be engaged in a business that harms no one. Indeed, many people think that the coyotes are providing a service to Mexico (by alleviating the poverty of thousands of families), and to the United States (providing needed workers). Migrants consider the coyotes to be a "necessary evil"—but one which could

Table 2
Coyotes: Principal Characteristics by Sphere of Operation

Type	Target Population	Logistics	Price Range	System of Payment	Advantages/ Disadvantages
Local only	Relatives; friends; word-of-mouth recommend-ation; limited geographical area	Access to a social network network in hometown; takes migrant to border; arranges crossing; meets migrant on U.S. side and delivers to destination	250-600 USD depend-ing on arrange-ment for crossing	Variable: -by family mem-ber or friend in U.S. upon safe delivery; -by family in hometown upon confirmation of safe delivery; -installments by the migrant him/herself from coyote-related employment	Personal safety; worry-in hometown; modest price range; suitable for the cautious person; possibility to get a job arranged by the coyote himself. High rate of failure
Local-Border	Word-of-mouth recommend-ation; wide geographical area; con-tacts in both hometown and border	Informal organization; contact made in places frequented by migrants (hotels, restau-rants), use of fake documents	400-900 USD depend-ing on arrange-ment of crossing	In almost all cases by family member or friend in U.S. upon safe delivery	Personal safety suitable for women and children. Higher prices.
Border only	Contacted at bus station, train, hotel, restaurant, near the border and other places frequented by migrants	Formal, struc-tured organiza-tion; use of cellular phones, beepers; cont-tact on both sides of border; pick-ups, fake documents, U.S. airports	600-1500 USD depend-ing on arrange-ment for crossing	Generally by family member or friend in US upon safe delivery	High probability of success. Expensive, vul-nerabiity during wait at border; lack of social support network

Source: Fieldwork, Gustavo López Castro, CER/Colmich, 1997

be much worse than it actually is. The local coyotes rank higher than the border coyotes for the obvious reasons of familiarity; but not even the border coyotes are perceived as being particularly nasty. Much more to be feared are nocturnal encounters with bandits or with one of the many groups of police that patrol the border area.

We found no evidence of collaboration between coyotes and drug traffickers in the towns; not even in the drug-producing areas of Michoacán. Interviews carried out with Border Patrol agents towards the end of 1996 also suggested few connections. We were told of cases in which migrants were urged to pay for part of the cost of being smuggled by also taking a small package along, but it is not clear how common this practice is, and it does not seem to be common for migrants to take packages from producing areas to the border.

The local coyotes and local-border groups appear to keep their distance from drug smuggling. Some of those associated with business coyotes may also be involved in drug smuggling, but there appears to be a firm line between the two activities due to the high risks involved in drug smuggling.[3]

Quotes from Smugglers/Migrants

Costs

> People come to us from, say, Leon, Guanajuato and when they get here they say; "Hey, I heard you take people across in airplanes. How much do you charge?" Then, "how much do I need to make it?" Then we say "look, from here to the border its 362 pesos right now, plus another $100 the jump, between $100 and $120 for the airplane ticket and you'd better have fifty or sixty dollars more for your expenses on the other side, like, I mean, for taxis, meals or whatever you need to spend; so we're talking about a total of around $300."

Contacts

> Back in San Felipe a lot of folks say that in Ocampo there are real good coyotes, real quiet, you know, good people. Here and anywhere you look there's lots of them, especially if you have friends or relatives, they'll set you up with one in a flash. Over in San Felipe it looks like they're charging about $500. It's a lot, but if you have good luck, and work hard, cause sometimes you can get caught, but if you work hard, in about three weeks, or at the outside a month, you pay it off; and from there on it's gravy.
>
> I used to make it as a wetback walking across country. It's all a question of finding contacts. The first three times I went I couldn't get any contacts, not even with the people that crossed with me. It'd take me eight or nine days to get to San Antonio, walking day and night; but then I started making contacts about

a three days' walk from here. I'd go to this farmer's place and ask for a chance to call San Antonio by phone. That's right, I'd get there at night and sit on the fence, the dogs would start to bark and the old man, an "old gringo," would come running over and I'd ask him "... gimme a chance to call my boss in San Antonio?" "How many guys are with you?" I'd say "three or four," "ok, bring 'em over, that's all right," and then he'd call and the boss would send someone over to pick us up. That's what I mean by contacts.

Guarantees

Up there at the border there's lots of coyotes, but there's no safer way than going with one right from here, like one's got more guarantee, more safety, it's somebody you know and you're with a group and they take better care of you, cause you never know what it's gonna be like up there. I mean, you always hope things will go well for you, but the way things are right now it's a bitch, and this way you're safe.

Up there, you could find yourself with a bunch of people who are just starting and... that's tough. But these guys from Mezquite come and go and if you don't get across but get caught, they take you back across again. Ya, they've got good contacts. If you got contacts that'll answer for you, you give them the telephone number and they call and then they take you to your house and they pay him there, but you're safe.

People come from all over to use this coyote; from Leon, and other places, they're finding out that these guys are doing well and so they come to look for them and they get comfort and they protect them. They've got their trucks to bring the folks this far; they've got a good setup. They take care of you here, and things are safe, you even go like friends with all the others; the other way you just gotta take your chances alone up there at the border. But here, here they take responsibility. They're good guys, once they take you on as a client, you go under their responsibility; the other way, up there at the border, who'll take you?, who knows?, who guarantees you anything?, who knows?.But these guys give you a guarantee.

My Way

I always like going across by way of Juarez, on a plane, for this reason: that way I don't run any risks, none, cause it's real hard for them to catch me among all the people; with all the people around they'll never grab me; if they get some, they're gonna get some of them, but not me. And if they do get me, they'll just take me like any other illegal migrant.

And when they get caught you just tell them "Know what, if they grab you I'll see it when they get you. Where they send you—there's three bridges or four—and you just stay there around the bridge where they send you back, don't

move, cause I'll go there to pick you up and send you back across again." That is, whoever wants to, right?; cause some say "know what, I'm not going again." So what do you do?, you say "gimme your ticket," you go and change it and then you got your money. But as long as the folks say they want to keep trying to get across, you gotta keep at it.

Papers

You get the cards in El Paso, Texas. They're lost or stolen. The thing is that they gotta look something like the migrant who wants to get across. You get a lot of these things by telephone. Then, when you make a connection you take things as they come... and you take your time cause you don't want to get in with just anybody. I mean, in these cases there are straight people and crooked ones, but with time you come to learn who you can work with and who you can't.

Ethics

Ok, so let's say... it's a crime, right?... but at the same time the person, the illegal migrant, the folks who want to get across, don't see it as a crime, but still they're grateful, they don't say... I mean... the fact is the people are never satisfied, they always say... one thing or another, look you didn't give us anything to eat, like what do I know, right?, but you know you gotta economize as much as you can cause you never know if they're gonna get across or if they're gonna get sent back from the airport.

Notes

1. We have included questions concerning the method chosen to cross the border in various questionnaires used in community studies. Among these we can mention the survey carried out by a group from the Colegio de Michoacán in 1983, 1986, 1988, and 1992 as well as 390 questionnaires which were applied in three towns in Michoacán and two towns in Jalisco in 1996.

2. The village connections explain how some families of migrants can pay off the cost of smuggling with dollar remittances to the family of the local coyote. Such a payment method would not be acceptable to border area coyotes.

3. A coyote in Guanajuato said that he cannot afford to take the risk of sending drugs along with migrants, who would be too nervous during the numerous police stops in Mexico.

Factors that Influence Migration

Factores de la Migración y Redes Migratorias

Jean Papail

El análisis de las corrientes de emigración anuales de algunas ciudades medias de Jalisco (Lagos de Moreno, Ciudad Guzmán, San Juan de los Lagos, Tepatitlán de Morelos) hacia Estados Unidos entre 1976 y 1993, sugiere la existencia de fluctuaciones importantes en la magnitud de estos flujos, estrechamente ligadas a la coyuntura económica. Los periodos de fuerte crecimiento económico en México (1978-81, 1984-85, 1989-92) se caracterizan por flujos de primera migración orientados a la baja o más o menos estables en sus volúmenes, mientras los periodos recesivos (1982-83, 1986-88) que acompañan las crisis monetarias, producen olas migratorias hacia el país fronterizo.

Según este modelo, el periodo actual debería caracterizarse por una nueva ola migratoria, producida por la devaluación de la moneda mexicana en diciembre de 1994, y el contexto recesivo en el cual se desarrolla la actividad en México. En efecto, varios factores inciden en la movilidad geográfica de la mano de obra: tasa de desempleo, diferencial de salarios entre los dos países, evolución del ingreso real.

Por otra parte, las economías norteamericana y mexicana evolucionan muy a menudo de manera desfasada en sus ciclos cortos durante los 20 últimos años, lo

que tiende a regular de cierta manera la magnitud de los flujos migratorios, aun si la tendencia de fondo a largo plazo de estos flujos está orientada a la alza.

En este trabajo nos concentraremos en las modalidades y condiciones de los desplazamientos, y la inserción de los migrantes en Estados Unidos, temas sobre los cuales la literatura disponible es menos abundante. Nuestra principal fuente de datos está constituida por una encuesta aleatoria realizada en diciembre de 1995 en una población de 801 migrantes y ex-migrantes masculinos de 2 ciudades del Estado de Jalisco, escogidas por sus fuertes tasas de emigración.

Para circunscribir mejor el cambio de contexto económico después de la devaluación de diciembre de 1994, hemos agregado a la muestra alrededor de 400 hogares en los cuales ningún miembro es migrante o ex-migrante a Estados Unidos. La elección de migrantes masculinos exclusivamente se debe al hecho de constituir una población homogénea, ya que se considera además que es la componente motriz del conjunto de los flujos, y que se trata esencialmente de migraciones de trabajo.

Ciertos datos de esta encuesta permiten comparaciones útiles con informaciones procedentes de una encuesta realizada a mediados de 1993 sobre las migraciones internacionales en las cuatro ciudades jaliscienses mencionadas anteriormente. Así, nos referiremos a veces a resultados de la encuesta de 1993, particularmente cuando se detectan cambios significativos en diversos aspectos de la migración.

Por fin hay que subrayar que la población estudiada aquí no pretende representar al conjunto de los flujos mexicanos. En varias regiones proveedoras de migrantes existen ciertas especificidades en cuanto a la relación rural/urbano, a la participación femenina en la composición de los flujos, a los lugares de destino en el país fronterizo (determinados en gran parte por la historia de sus redes migratorias), a las actividades desempeñadas por los migrantes del otro lado de la frontera, etc. Sin embargo pensamos que ciertos cambios importantes en los últimos años en la emigración urbana jalisciense pueden contribuir a aclarar transformaciones más globales que están apareciendo en ciertos aspectos en los flujos mexicanos.

El contexto socioeconómico actual (1994-95)

Los dos indicadores más importantes (actividad e ingreso) en materia de movilización de la mano de obra mexicana hacia Estados Unidos sufrieron fuertes cambios con la crisis económica que estalló con la devaluación de la moneda mexicana en diciembre de 1994.

Después de un corto periodo de relativa estabilidad del ingreso real (1991-1994), la devaluación crea una nueva ruptura en la evolución de este indicador. El índice de salario mínimo real nacional que se ubicaba en 44.1 en febrero de 1989 (base 100 en 1980), 40.0 en noviembre de 1991 y 38.7 en noviembre de 1994, se

reduce al 31.2 en noviembre de 1995.[1] Por otra parte, la tasa de desempleo abierto a nivel nacional, que oscilaba entre 2.5 y 3.5% durante los primeros años de la década, alcanza 7.3% en septiembre de 1995.

Los datos de la encuesta sobre migraciones que levantó el INSER-U de G/ ORSTOM en diciembre de 1995 ilustran el cambio del contexto socioeconómico entre 1994 y 1995:

- Se observa un estancamiento del ingreso promedio mensual por hogar entre estos dos años (mil 791 pesos en 1994 y mil 837 pesos en 1995), lo que corresponde en términos reales a un fuerte deterioro del nivel de vida de estos hogares (cuadro 1). Más de la mitad de los hogares consideran que sus ingresos se quedaron al mismo nivel o disminuyeron entre estos dos años (cuadro 2). En este contexto, el nivel del monto de las remesas enviadas por los migrantes internacionales se vuelve un elemento cada vez más importante en la estructura de los ingresos de los hogares (cuadro 3).

Cuadro 1
Ingresos promedios mensuales por hogar (pesos)

	1994	1995	
En pesos (N)	1414 (196)	2010 (220)	(335 dólares cambio = 6P/1USD)

- Se observa igualmente un nivel elevado de desempleo que se manifiesta por el hecho de que en cada hogar se perdió en promedio cerca de 0.5 empleos durante el año 1995. El porcentaje de hogares afectados por el desempleo de uno o más miembros del grupo familiar se avecina al 30%; lo que explica en gran parte la evolución observada del ingreso hogareño.

Unicamente alrededor del 30% de los desempleados pudieron encontrar un nuevo empleo durante el año de 1995 en su ciudad de residencia. Un reflejo de esta situación se encuentra en la proporción de desempleados entre los migrantes internacionales en el momento del primer desplazamiento a Estados Unidos. Este indicador se ubicaba en 11.1% durante el periodo 1985-1989; 12.9% durante los años 1990-1993 y subió al 17.5% durante los dos últimos años (1994-1995).

Se puede presentar esta situación de manera sintetizada. La relación del tamaño promedio del hogar respecto a sus miembros económicamente ocupados; la relación que fluctuaba entre 3.1 y 3.4 miembros por ocupado durante el periodo 1985-1993 se deterioró fuertemente durante los dos últimos años cuando alcanzó el valor de 4 miembros por ocupado (cuadro 4).

El crecimiento del desempleo y el estancamiento de los ingresos hubieran podido ser agravados por eventuales situaciones de endeudamiento respecto al sistema bancario u otras instituciones por la fuerte alza de las tasas de interés que produjo la devaluación y el fuerte incremento de la inflación que la siguió. Sin embargo se observa que apenas 10% de los hogares están endeudados a fines del 95, de los

Cuadro 4

1985-1989	1990-1991	1992-1993	1994-1995
3.4	3.1	3.4	4.0

cuales un tercio renegoció sus deudas o lo están haciendo, y cerca del 10% no considera que este nuevo contexto empeoró su situación en este aspecto.

Esta situación de estancamiento de los ingresos nominales y de incremento del desempleo fue en parte compensada por la incorporación de nuevos miembros de los hogares a los mercados de trabajo locales (adolescentes, mujeres dedicadas anteriormente a los quehaceres domésticos, etc.)

En 1995, en un tercio de los hogares de no migrantes que sufrieron pérdidas de empleos se incorporó por lo menos un miembro suplementario al mercado de trabajo respecto al 23% de los hogares que no sufrieron desempleo de sus miembros (en los hogares de migrantes actuales y de ex-migrantes estos porcentajes se ubican respectivamente en 22 y 18.5%). Esta incorporación de miembros suplementarios al mercado de trabajo representa 0.16 hombres y 0.16 mujeres en los hogares donde no hubo desempleo, y 0.28 hombres y 0.22 mujeres en los hogares donde por lo menos uno de sus miembros sufrió desempleo. Como se puede observar, los miembros femeninos de los hogares fueron muy solicitados para superar el deterioro de la situación económica en 1995 (cuadro 5). Según estos datos el saldo global de las salidas (por desempleo) del mercado de trabajo y de las nuevas incorporaciones a éste, fue ligeramente positivo, gracias sobre todo al componente femenino. Sin embargo, es probable que buena parte de estos nuevos empleos corresponda a trabajos de tiempo parcial y/o mal remunerados

Otra respuesta de las familias al deterioro del contexto económico fue la creación de un negocio familiar que se dio en alrededor de 15% de los hogares. Las pérdidas de empleo no parecen tener mucha influencia en este aspecto. Por otra parte, se observa que solamente alrededor de 8% de los desempleados que lograron emplearse en 1995 lo hicieron bajo el estatuto de “auto-empleo” (por cuenta propia).

Cuadro 5
Promedio de miembros de los hogares recién incorporados al marcado de trabajo por sexo y pérdidas de empleos en 1995

	Hombres	Mujeres
SIN PÉRDIDAS DE EMPLEOS		
hogares de ex-migrantes ctuales	0.13	0.16
hogares de ex-migrantes	0.14	0.13
hogares de no migrantes	0.20	0.19
CON PÉRDIDAS DE EMPLEOS		
hogares de ex-migrantes	0.24	0.19
hogares de migrantes actuales	0.32	0.17
hogares de no migrantes	0.27	0.29

Finalmente una de las consecuencias más importantes del brusco cambio del contexto económico se refleja en la movilización geográfica de la mano de obra, como suele ocurrir en estas situaciones. En 16% de los hogares que no sufrieron desempleo durante el año 1995, se observó emigraciones de las ciudades en las cuales se ubican estos hogares. Esta proporción sube al 27% cuando los hogares tuvieron al menos un miembro desempleado durante 1995.

Se puede comparar la distribución por ramas de los empleos que encontraron los desempleados cuando lograron reinsertarse en los mercados locales de trabajo con las aspiraciones, reflejo de las opiniones sobre las ramas que ofrece las mejores oportunidades de trabajo y/o ingresos (cuadro 6).

Como se puede constatar, las opiniones (o aspiraciones) difieren notablemente de la situación real en 1995. Esta brecha se debe en gran parte a las aspiraciones al auto-empleo (alrededor de 50% de las opiniones respecto al 8% en los casos de reinserción) que se concentra fuertemente en la rama comercio (cerca del 66% de las aspiraciones a establecerse por cuenta propia). Como se demostró en trabajos anteriores, esta aspiración al auto-empleo es un factor relativamente importante de la movilidad territorial en la medida que necesita un cierto periodo de acumulación de capitales que casi exclusivamente se puede realizar en una economía como la de Estados Unidos que ofrece salarios netamente superiores a los de las economías locales. Como lo veremos mas adelante, el diferencial de salarios promedio entre Jalisco y Estados Unidos se ubica en alrededor de 8 a fines de 1995, respecto a 4.5 en 1993 (el salario promedio percibido por los migrantes en Estados Unidos en 1993 equivalía a 4.5 salarios promedios percibidos en los lugares de origen).

Por otra parte, alrededor del 30% de los ex-migrantes —reinstalados para 90% de ellos con más de un año en sus lugares de origen— consideran, en este contexto

Cuadro 6

(N)							(904)

recesivo de la economía mexicana, volver a irse a Estados Unidos. Esta proposición alcanza 39% ente los migrantes de retorno de menos de 4 años.

Del otro lado de la frontera, la recuperación de la economía norteamericana durante los tres últimos años después de la recesión del inicio de la década, que se manifiesta por tasas de crecimiento del orden de 3% anual y tasa de desempleo abierto alrededor del 5.5% reactivó la demanda de trabajo, lo que concurre a estimular la movilización de mano de obra mexicana.

Para concluir, la fuerte recesión de la economía mexicana en 1995 y 1996 produjo un contexto muy propicio al desencadenamiento de una nueva ola migratoria de mano de obra (como ocurrió en 1983-84), a pesar del endurecimiento de la política migratoria por parte de Estados Unidos. No existen señales al inicio de 1996 que se alcanzaron los puntos de inflexión en la evolución de los principales indicadores que utilizamos aquí, que podrían predecir una inversión de tendencia en la evolución de la magnitud de los flujos.

Las modalidades de la migración y las redes migratorias

Las características de los migrantes al momento de la primera migración

La edad promedio a la primera migración osciló alrededor de los 23 años en todos los periodos considerados. Sin embargo parece haber subido fuertemente (27.8 años) durante los dos últimos años, debido a una modificación de la composición de estos flujos. En 1994 y 1995, la proporción de jefes de hogares en los flujos alcanzó 46% mientras se ubicaba alrededor del 35% durante los periodos anteriores. Con una edad al desplazamiento netamente más elevada (30.2 años) que la de los individuos con estatuto de hijos en los hogares de salida (20.1 años), este componente, cuyo peso relativo se refuerza en los flujos, hace subir la edad promedio del conjunto. Esto se refleja en la proporción de casados en los movimientos, que pasa del 32% antes de 1990 al 38% durante los últimos años. Durante este último periodo se observa un fuerte aumento de la proporción de casados entre los jóvenes adultos migrantes (20-24 años). Representan actualmente 36% del grupo de edades contra 11% durante los periodos anteriores.

Por otra parte, se observa también un aumento del tamaño (número de personas) de los hogares cuyos jefes son migrantes desde el inicio de la presente década. El tamaño de estos hogares sube de 4.4 miembros durante el periodo 1985-1989 a 5.5 en 1994-1995, lo que incide, como se mencionó anteriormente en la evolución de la carga consumidores/activos ocupados.

Se puede considerar que la migración retrasa la realización de matrimonios como se observó en otros estudios (R. Pimienta Lastra, 1995). Según nuestros datos

la edad promedio al matrimonio en la población masculina se ubica en 22.3 años cuando estos matrimonios se realizan antes de la primera migración; pero sube al 25.2 años cuando este evento está precedido por el desplazamiento a Estados Unidos.

El nivel educativo de la población migrante subió de manera constante a lo largo de los años pero parece haber retrocedido durante los años 1994-95, lo que se puede asociar en parte a la alza de la proporción de migrantes que provienen de la rama agrícola en los flujos recientes. De manera general este nivel educativo es ligeramente inferior al de la población mexicana en general como lo señalan diferentes estudios (R. Corona, 1995). Es posible que la crisis económica incrementó el nivel de deserción escolar de los adolescentes que participan en los flujos migratorios. La elevación de la edad promedio a la migración influye también en este deterioro del nivel promedio de escolaridad.

Como se mencionó anteriormente, se observa un incremento de la proporción de desempleados en los flujos de salida durante los dos últimos años sobre todo en la población de no jefes de hogares. Entre estos últimos migrantes, la proporción de desempleados se ubicó en 19.4% en 1994-1995 respecto al 12.1% durante los 4 primeros años de la década.

La distribución de las ramas de actividad de los migrantes ocupados según el periodo de salida (cuadro 7) confirma lo que habían revelado estudios anteriores (Papail y Arroyo, 1995): una diversificación progresiva de las actividades de origen de los migrantes, en detrimento de la agricultura que proveía alrededor de la mitad de los flujos migratorios antes de 1980.

La evolución de la estructura de los ingresos percibidos por los activos antes de migrar hace aparecer un mejoramiento sensible: en 1994-1995, 73% de los migrantes percibían ingresos iguales o inferiores a 2 salarios mínimos respecto al 85% entre los migrantes del periodo 1985-1989. Sin embargo se pueden comparar estos datos con los de 1993 (Papail y Arroyo, 1995) concernientes a las mismas ciudades. En esta fecha, alrededor del 60% de los activos ocupados de Ciudad

Cuadro 7
Ramas de origen de los migrantes según el periodo de migración

Periodo	Agricultura	Industria	Construcción	Comercio	Servicios	Otras	Total
Antes 80	49.8	9.6	10.5	9.1	15.5	5.4	100
80-84	22.7	25.3	13.3	10.7	21.3	6.6	100
85-89	16.9	27.3	16.3	11.0	23.8	4.6	100
90-93	11.6	27.5	14.5	15.2	23.2	7.9	100
94-95	16.9	32.3	7.7	13.8	20.0	9.2	100

Guzmán y Lagos de Moreno percibían a lo más 2 salarios mínimos. Los migrantes parecen pues conformar una sub-población con ingresos ligeramente inferiores al promedio de la población de sus ciudades de origen, particularmente los que provienen de la rama agrícola donde se encuentra la fracción más importantes de ingresos inferiores o iguales a 2 salarios mínimos.

Los proyectos que formulan los migrantes al desplazarse a Estados Unidos son relativamente constantes en su distribución entre las diferentes épocas de migración. Alrededor del 20% no tienen proyectos bien definidos. Entre los que tienen un proyecto principal (o prioritario) elaborado, la compra de una casa o de un terreno representa la perspectiva que aparece con más frecuencia (entre 25 y 30%). Entre 8 y 15% según los periodos de migración, manifiestan el deseo de establecerse por cuenta propia a su futuro regreso a su ciudad de origen después de trabajar varios años en el país fronterizo, y 10 a 15% formulan como proyecto prioritario un futuro matrimonio.

Una proporción relativamente importante (20 a 25%) considera el desplazamiento a Estados Unidos como la mejor opción para "progresar", mejorar su situación económica", etc. Naturalmente, los migrantes casados antes de migrar formulan generalmente proyectos mejor definidos que los solteros. El objetivo de comprar una casa o un terreno aparece mucho más frecuentemente en este grupo que entre los solteros. La realización de este objetivo es muy frecuente si se considera que 87% de los jefes de hogares al migrar antes de 1980, que no tenían casa propia antes de desplazarse, son actualmente, después de su regreso, dueños de su vivienda (esta proporción alcanza 61% entre los migrantes de 1980-1984; 56% entre los migrantes de 1985-1989 y 35% entre los que salieron en 1990-1993).

Las condiciones del primer desplazamiento a Estados Unidos

La elaboración del proceso de decisión de migrar a Estados Unidos parecer ser mayoritariamente un proceso personal: alrededor del 75% de los migrantes afirman haber elaborado este proyecto personalmente, tanto entre los jefes de hogares como entre los individuos que tenían el estatuto de "hijo" en el momento del desplazamiento.

La influencia del grupo familiar en la generación del proyecto migratorio aparece en alrededor del 15% de los casos en todos los periodos anteriores a 1993. Su importancia relativa creció considerablemente durante los dos últimos años, representando 24% de los casos en la población de "hijos" en detrimento de la influencia de los amigos. Un aspecto interesante a señalar es que cuando la generación del proyecto migratorio no proviene del migrante mismo, la persona que originó el proyecto reside con mayor frecuencia en Estados Unidos en el

transcurso del tiempo (53% de estas personas residían en el país fronterizo en 1980-1984; 75% en 1990-1993 y 85% en 1994-1995).

Esta intervención externa está frecuentemente asociada a la existencia de un empleo asegurado para el migrante a su llegada a Estados Unidos, generalmente en la agricultura o en la construcción. La seguridad de tener un empleo al llegar del otro lado de la frontera creció fuertemente desde el inicio de la década de los ochenta: 15% de los que salieron en los años1980-1984 se encontraban en esta situación, y respectivamente 20%, 26% y 32% en los periodos 1985-1989, 1990-1993 y 1994-1995, gracias a la fuerte presencia de familiares o amigos en este país. Este aspecto deja entrever igualmente el papel relativamente importante de la demanda de trabajo en la generación de los flujos migratorios.

Desde mediados de los ochenta, la proporción de indocumentados en los flujos de primera migración parece haberse reducido. Del 87% durante los años 1980-1984, esta proporción bajo al 84% en 1985-1989 y 78% y 80% respectivamente en 1990-1993 y 1994-1995. Sin embargo, la distribución de los tipos de documentos con los cuales los migrantes cruzan la frontera muestra el peso preponderante y en progresión constante de las visas turísticas en el transcurso del tiempo. Este tipo de documentación representaban 43% de los documentos requeridos para ingresar legalmente a Estados Unidos en 1980-1984, 66% en 1985-1989, 72% en 1990-1993 y 86% durante los dos últimos años. Esto indica que la migración "legal" de mano de obra es sensiblemente más baja que lo que aparece en los datos brutos de la encuesta.

El endurecimiento de la política migratoria de Estados Unidos, que se manifiesta en particular por la intensificación de la vigilancia de la frontera californiana desde hace unos años parece haber producido una redistribución de los lugares de ingreso a este país. Además de un uso más importante del transporte aéreo por parte de los poseedores de visas turísticas desde 1993, existe una diversificación creciente de los lugares de cruce terrestre de la frontera durante los años 1994-1995. Tijuana, por donde cruzaban 78% de los migrantes indocumentados durante los años 1980-1984, y 95% durante el periodo 1985-1993, no representa más de 56% de los lugares de cruce de los indocumentados que se desplazaron en 1994-1995. Esta diversificación se produce en provecho de Nogales (13% de los cruces de indocumetados en 1994-1995 contra 4 a 6% en los periodos anteriores) y otras ciudades fronterizas no californianas.

Esta diversificación se refleja igualmente en los destinos de los migrantes indocumentados. Mientras California representaba entre 80 y 85% de los destinos de los indocumentados durante la década de los ochenta, su peso relativo en la distribución de los destinos de estos migrantes bajo al 76% en 1990-1993 y 67% durante los dos últimos años.

Son esencialmente otros Estados, Illinois y Texas (que representan con California los destinos tradicionales de la migración jalisciense), los que se

beneficiaron de esta redistribución geográfica. Se observa el mismo fenómeno en el territorio californiano: Los Angeles, San Francisco y San Diego que absorbían generalmente alrededor de 50% de los flujos dirigidos hacia ese Estado, no representan más que un tercio de los destinos de los migrantes mas recientes (1994-1995).

La proporción de indocumentados en la migración dirigida hacia California fue siempre netamente superior a las de los flujos que se dirigen hacia otros Estados, y no parece haber cambios significativos en este aspecto durante los últimos años.

Alrededor de 77% de los migrantes indocumentados usaron los servicios de un pollero para cruzar la frontera durante los años 1980-1993. Parece haberse intensificado este uso desde 1993, si se considera que 86% lo hicieron durante los dos últimos años, a pesar del fuerte aumento de este costo (de 310 dólares en promedio en 1994 a 380 dólares en 1995).

Paradójicamente, el reforzamiento de la vigilancia en la frontera no parece haber producido mayores dificultades para los indocumentados: entre 55% y 60% de estos migrantes lograron cruzar la frontera en su primer intento en 1994 y 1995, proporción ligeramente superior a lo que ocurría en los periodos anteriores (alrededor del 53%).

Los dos últimos años se señalan igualmente por el cambio ocurrido en la estructura del financiamiento del desplazamiento. Hasta 1993, más de la mitad (entre 53% y 58% en todos los periodos) de los costos asociados al desplazamiento estaban financiados por los ahorros del propio migrante. Esta proporción bajó al 38% durante los dos últimos años cuando se usaron más préstamos (29%) otorgados sobre todo por el grupo familiar residiendo en México y otras fuentes de financiamiento (incluyendo regalos). Esta mayor necesidad de financiamiento externo refleja los cambios reciente ocurridos en los destinos (peso relativo más importante de los Estados no fronterizos en el territorio norteamericano) que aumentan los costos del desplazamiento, como el aumento de estos costos después de la devaluación del peso.

Las modalidades de inserción en estados unidos

Cerca del 95% de los migrantes que salieron por primera vez a Estados Unidos en1994-1995 tenían un pariente y/o un amigo en su lugar de destino (76% tenían a un pariente y 55% a un amigo). Esta proporción es constante entre los migrantes desde mediados de los ochenta y era ya relativamente alta al inicio de esta misma década (82%).

Se observa la misma redistribución de los lugares de residencia de los conocidos de los migrantes en el transcurso del tiempo: California que absorbió

alrededor del 75% de los flujos durante la década de los ochenta, no representa más que 65% de los destinos de los familiares y amigos que migraron entre 1990 y 1995; mientras los destinos no tradicionales (otros Estados como Texas e Illinois) captaron 18% de los flujos más recientes respecto al 8-10% durante la década de los ochenta.

Esta presencia de parientes o amigos en el lugar de destino tiene gran importancia porque facilita la inserción del migrante recién llegado en este nuevo contexto.

Una de las formas más frecuentes de ayuda que se le proporciona al recién llegado está representada por el hospedaje. Desde hace una decena de años, la casi totalidad (95%) de los nuevos migrantes se benefician de esta ayuda que les brindan los parientes o amigos que residen en el lugar de destino. Esta facilidad alcanza cerca del 100% de los migrantes que se dirigen a Illinois desde el inicio de la década de los ochenta, expresión de la antigüedad de las redes migratorias en este Estado. En los Estados de destino no tradicional, esta ayuda beneficia actualmente a cerca del 90% de los migrantes.

La mayor parte de los migrantes hospedados a su llegada a Estados Unidos (50 a 60% según los periodos) lo están por una duración superior a un mes, sobre todo entre los documentados. Generalmente el hospedaje proporcionado por los conocidos es gratuito (55% de los casos), pero la participación financiera por parte del migrante se vuelve mayoritaria a partir de los dos meses de hospedaje.

Al hospedaje está estrechamente asociada la alimentación para el recién llegado, y las mismas observaciones (duración, forma) anteriores pueden hacerse respecto a esta otra forma de ayuda.

Alrededor del 75% de los empleos encontrados por los recién llegados lo son por mediación de los parientes o amigos que residen en el lugar de destino. Desde 1985, solamente 10 a 15% de los empleos fueron encontrados por los migrantes sin intervención externa.

Fuera de California y Texas, esta búsqueda personal es muy poco frecuente (sobre todo en Illinois), lo que denota proyectos migratorios mejor preparados (o menos aleatorios) en el aspecto de la inserción profesional por parte de los migrantes que se dirigen hacia estos Estados. Este aspecto se refleja igualmente en la proporción de migrantes que estaban seguros de tener un empleo determinado a su llegada a Estados Unidos. En los dos últimos años por ejemplo, 14% de los migrantes que llegaron a California tenían un empleo asegurado respecto al 57% entre los que se fueron a Illinois y otros Estados (excepto Texas).

La proporción de migrantes documentados que tenían un trabajo asegurado al desplazarse se ubica entre 25 y 30% en todos los periodos. Esta asociación "migrante documentado" "trabajo asegurado" que estaba muy fuerte antes de 1980, sobre todo en la agricultura, se debilitó mucho en el transcurso del tiempo, aun si presenta todavía una relativa importancia en la rama de la construcción.

Por otra parte, se observa una fuerte reducción de la precariedad en este grupo de migrantes en la medida que antes de 1980, por el peso de la agricultura (y la estacionalidad de sus empleos) en la absorción de estos flujos, más de la mitad (60%) de los que tenían un trabajo asegurado al migrar, lo tenían por una duración inferior o igual a 6 meses, mientras son apenas 10% en esta situación los que migraron entre 1990 y 1995.

El tiempo requerido para encontrar un empleo estuvo alargándose desde el inicio de la década de los ochenta hasta 1993: 24% de los recién llegados necesitaban 4 semanas o más para insertarse en el mercado laboral en 1980-1984, respecto al 31% en 1985-1989 y el 35% durante el periodo 1990-1993. Durante los dos últimos años (1994-1995) esta tendencia se invirtió y la inserción profesional se realiza mucho más rápidamente: solamente 25% de estos nuevos migrantes necesitan un mes o más para encontrar un empleo.

Generalmente se puede considerar que la inserción en los mercados locales de trabajo se realizan más rápidamente en Texas y en otros Estados de destino no tradicional. De igual manera los migrantes documentados encuentran más rápidamente un empleo que los indocumentados. Casi 2/3 del primer grupo están trabajando a más tardar 2 semanas después de su ingreso en Estados Unidos respecto al 53% en el segundo grupo durante los dos últimos años.

En términos de ramas de actividad, esta inserción ocurre generalmente mucho más rápidamente en la agricultura y en la construcción aunque en los años recientes únicamente esta última ofrece posibilidades de encontrar un empleo con rapidez, probablemente porque es ahí donde se cuenta la más alta proporción de trabajadores documentados entre todas las ramas que absorben los flujos de mano de obra. Si antes de la década de los ochenta, era en la rama agrícola donde se encontraba la más alta proporción de trabajadores documentados entre su mano de obra, esta rama fue desplazada en este aspecto por la industria durante el periodo 1985-1993, y por la construcción actualmente.

Hubo una diversificación progresiva en la estructura de las ramas de actividad en las cuales se insertan los migrantes en Estados Unidos a partir de la segunda mitad de los años setenta. Antes de esta fecha más de la mitad de los migrantes originarios de las ciudades medias de Jalisco se empleaban en la agricultura a su llegada en el país fronterizo (Papail y Arroyo, 1995). Esta proporción bajó al 16% durante el periodo 1990-1993, pero parece tener un ligero repunte (21%) actualmente (1994-1995). La diversificación se produjo en provecho de la industria, de la construcción, de los restaurantes-hoteles y de los servicios (cuadro 8). Globalmente California destaca por la importancia de sus ramas construcción y servicios en la absorción de sus inmigrantes, Illinois por su industria, y Texas y los otros Estados por su agricultura.

El desplazamiento a Estados Unidos se acompaña generalmente de cambios de actividades entre el lugar de origen y el lugar de destino. Tomando el grupo de ramas

Cuadro 8
Ramas de actividad de los inmigrantes a su llegada a Estados Unidos por periodo de migración

90-93	16.0	14.1	25.0	19.9	19.2	5.8	100
94-95	20.6	17.6	30.9	13.2	14.7	2.9	100

constituido por la agricultura, la industria y la construcción, se observa que desde el inicio de los ochenta, solamente entre 26 y 32% de los migrantes provenientes de estas ramas siguen trabajando en las mismas actividades al llegar a Estados Unidos. Es sobre todo en la agricultura donde se observó la retención más importante de mano de obra a través de la migración y en menos medida en la construcción, aún si desde el inicio de los noventa, los migrantes provenientes de la agricultura mexicana tienen una movilidad parecida a los migrantes provenientes de las otras ramas.

Los empleados (o contratistas) de los migrantes son en su mayoría anglo-sajones (alrededor del 42%) o de origen mexicano (mexicanos o chicanos: 43%). El primer grupo es mayoritario en la agricultura y la industria, pero esta sub-representado en los servicios y restaurantes-hoteles. Al contrario se observa una sobre-representación de los contratistas y empleadores de origen mexicano en las ramas de la construcción y de los restaurantes-hoteles. El tercer grupo de empleadores o contratistas en el cual predominan los norteamericanos de origen asiático están muy concentrados en la rama restaurantes-hoteles.

En cuanto a las relaciones de trabajo, los migrantes desempeñan sus actividades en un contexto mayoritariamente latino desde hace mucho tiempo, pues casi 2/3 (64%) de sus superiores directos, y alrededor del 90% de sus colegas de trabajo son de origen mexicano. La presencia de la jerarquía anglosajón aparece esencialmente en la industria. Al contrario, la jerarquía de origen mexicano esta sobre-representada en la agricultura y sobre todo en la construcción y los servicios.

Geográficamente, se observa que los empleadores o contratistas anglosajones son netamente mayoritarios fuera de California, mientras los empleadores de origen mexicano son sub-representados en Texas y en los Estados de destino no tradicional.

Comparando los datos de diciembre de 1995 con los datos concernientes al periodo1991-1993[2] , parece haber ocurrido un aumento sensible de los ingresos

percibidos por los migrantes en Estados Unidos entre las dos fechas. El salario promedio percibido según estas fuentes sube de 5.6 dólares/hora (alrededor de 250 dólares/semana) en 1991-1993 a 8.3 dólares/hora (alrededor de 350 dólares/semana) a fines de 1995. Aparte de posibles diferenciaciones producidas por la técnica de muestreo entre las dos fuentes, varios factores concurren para explicar esta fuerte alza de los ingresos:

- El aumento sensible de la demanda de trabajo a partir de 1993, después de la recesión económica del inicio de la década, sobre todo en California, lo que favorece el incremento de los salarios.
- La modificación de la estructura de las ramas de actividades en las cuales se emplean los migrantes, como beneficio de actividades generalmente mejor remuneradas como en la rama de la construcción.
- El aumento reciente de la edad promedio a la migración, que moviliza mano de obra más experimentada.
- Una posible modificación de la relación documentados/indocumentados en favor del primer grupo (se considera que los indocumentados perciben en general un salario inferior del 20% al salario de un documentado, Papail y Arroyo 1995).

Esta evolución del nivel de los salarios es coherente con la evolución del nivel de las remesas mensuales (alrededor de 260 dólares en 1991-1993 a cerca de 330 dólares en 1995).

En todos los periodos de migración, alrededor del 40% de los migrantes proyectaban quedarse menos de un año en Estados Unidos. La misma proporción (40%) consideraba una estancia de duración indeterminada, mientras una muy débil fracción (3 a 4%) pensaba establecerse definitivamente en el país fronterizo. No se observan variaciones significativas en este aspecto en el transcurso del tiempo. Sin embargo los flujos dirigidos hacia Illinois parecen de más larga duración de estancia o con mayor frecuencia (7%) como de establecimiento definitivo.

El factor que parece tener la influencia más importante en la duración de estancia proyectada en Estados Unidos se refiere a los proyectos elaborados al momento de migrar. Cuando se trata de proyectos bien definidos (casarse, comprar una casa o un terreno, establecerse por cuenta propia al regreso), las duraciones de estancia son relativamente cortas, lo que es paradójico en varios casos. Al contrario el proyecto general (“mejorar”, “progresar”... etc.) está netamente con mayor frecuencia asociado a la duración “indeterminada”, Por otra parte, se observa que los migrantes documentados tienen generalmente proyectos de estancia más cortos. Esto se debe en buena parte a su peso relativo en la rama agrícola donde los requerimientos de mano de obra son a menudo estacionales.

En todos los periodos considerados, alrededor del 60% de los migrantes indocumentados pensaban tramitar la regularización de su presencia en el territorio norteamericano; cualquiera que sea el Estado de residencia, excepto en Texas donde menos del 50% de los migrantes formularon este proyecto.

El hecho de planear la regularización de su situación parece estar relacionado con el proyecto de traer más tarde a parientes o a veces a amigos. En efecto, 46% de los indocumentados que pensaban regularizarse formulaban este proyecto contra 22% entre los que no proyectaban regularizarse. Globalmente, cerca del 40% de los migrantes documentados tenían este proyecto de traer más tarde a parientes a Estado Unidos. Esta proporción no alcanza el 30% entre los indocumentados generalmente, pero parece estar en aumento desde mediados de los ochenta (33%) con la implementación de la ley IRCA.

El proyecto de traer parientes es más frecuente entre los migrantes que residen en Illinois (41%) y en California (37%) que entre los que residen en otros Estados (32%), y aumenta generalmente con el tiempo de estancia proyectado. Los migrantes documentados que piensan traer a parientes se refieren en alrededor del 70% a esposas e hijos, y para los 30% restantes a hermanos (15%) y amigos (15%), mientras los indocumentados distribuyen sus prioridades de manera diferente (55% de esposas e hijos, 28% de hermanos y 17% de amigos).

Los motivos enunciados por los migrantes que quieren traer a sus parientes o amigos se refieren generalmente a la reunificación familiar ("estar juntos") cuando se trata de esposas e hijos (84% de estos casos) o al tema general del mejoramiento de la situación personal ("mejor vida en Estados Unidos", "más oportunidades de trabajo", "ayudar") cuando se trata de hermanos, otros parientes o amigos.

Entre los migrantes que no pensaron traer a parientes o amigos al país fronterizo (64% de los migrantes), los motivos más frecuentes se refieren a condiciones de vida muy difíciles ("sufrimientos", "ambiente peligroso", etc. 37% de los casos), o porque el migrante no pensaba quedarse mucho tiempo en este país (11%) o, a veces porque el migrante atrasaba la formulación de ese proyecto hasta estabilizar su situación allá (acomodarse mejor, empleo menos precario...).

Entre los migrantes actuales (que residen en Estados Unidos en diciembre de 1995), 61% son casados. En este grupo, 41% de las esposas residen igualmente en el país fronterizo. Esta frecuencia es de 23% cuando el matrimonio ocurrió antes de la migración (y apenas 28% cuando el migrante salió por primera vez antes de 1991); pero alcanza la mitad (49.7%) cuando la primera migración precedió el matrimonio[3], lo que refleja la diversidad de los proyectos según el orden cronológico de estos eventos. La presencia de esposas en Estados Unidos es mucho más frecuente entre los migrantes casados documentados (54%) que entre los indocumentados (38%).

Las perspectivas

Entre los migrantes de retorno a sus lugares de origen, la duración de estancia promedio en Estados Unidos se ubica alrededor de 7.5 años en todos los periodos de regreso. Esta estancia en el país fronterizo es mucho más larga (alrededor de 10 años) cuando los migrantes estaban en situación legal que cuando se trata de migrantes indocumentados (alrededor de 6 años). La edad promedio al regreso oscila alrededor de los 30 años en todos los periodos. Generalmente, cerca del 60% de los migrantes se reincorporaron a su regreso en las ramas de actividad en las cuales desempeñaban sus actividades antes de migrar.

Los datos de la encuesta confirman lo que se mencionó en trabajos anteriores (Papail y Arroyo, 1995) sobre el deslizamiento de la distribución de las actividades del sector primario hacia el sector terciario a través del ciclo migratorio (cuadro 9). La agricultura y la industria que proveyeron el 51% de la mano de obra migrante (antes del desplazamiento), no absorben más que el 29% de esos migrantes a su regreso a México. Al contrario el comercio y los servicios que proveyeron 31% de la mano de obra integran 50% de los migrantes de retorno.

Entre los ex-migrantes, alrededor del 30% consideran regresar de nuevo a Estados Unidos debido al contexto recesivo actual de la economía mexicana, proporción que sube a casi 50% entre los migrantes de retorno de menos de 2 años, pero que apenas alcanza el 16% entre los que regresaron hace 6 años o

Cuadro 9

							(360)

más. Este proyecto es más frecuente entre los solteros (34%) que entre los casados (27%).

La reinserción de los migrantes en las economías locales se produce más o menos fácilmente según el periodo de regreso. Los individuos que regresaron alrededor del año de 1990 se beneficiaron con un contexto más favorable en su reinserción en los mercados de trabajo locales, durante una época de crecimiento sostenido de la economía mexicana y una demanda de trabajo en expansión. Muchos pudieron realizar sus proyectos de establecerse por cuenta propia gracias a la subvaluación de la moneda mexicana durante estos años (Papail y Arroyo, 1995).

Este regreso fue ocasionado en muchos casos por la constitución de nuevos hogares, misma que se había aplazado a causa de la migración laboral; por la compra de casas, y de manera general, por un cierto arraigo que reduce la propensión de "irse a volver" a Estados Unidos.

Las condiciones de reinserción se volvieron mas difíciles, sobre todo a partir de 1993 cuando empezó a contraerse el mercado de empleo con la sobrevaluación del Peso. Hay que subrayar la proporción todavía no despreciable (10 a 16%) entre los que regresaron hace más de 1 año, de los que consideran auto-emplearse o comprarse una casa (cuadro 10). Se observa que los jefes de hogares que tienen casa propia, son individuos que pasaron generalmente 9 o 10 años en promedio en Estados Unidos, duración netamente superior a los jefes de hogares regresados sin tener casa propia actualmente (alrededor de 6 años de estancia), lo que deja entrever que la realización de este tipo de proyecto (tener casa propia) necesita una cierta duración de trabajo en el país fronterizo.

Se puede pues considerar que actualmente existen probabilidades relativamente elevadas de re-emigración entre los ex-migrantes regresados durante los últimos 5 años. Hay que recordar que los primeros años de la década de los noventa se señalaron por una importante ola de regresos a México, lo que sugiere la existencia de un potencial de re-migrantes importantes en esta población.

En la población de migrantes actuales (que residen en 1995 en Estados Unidos), cerca del 80% piensan seguir trabajando en el país fronterizo. La situación migratoria (indocumentados o no) no parece influir mucho en los proyectos de residencia: 83% de los indocumentados manifiestan su interés en seguir trabajando cierto tiempo en Estados Unidos respecto al 76% de los individuos en situación regular.

Los proyectos derivados y asociados al regreso al lugar de origen (establecerse por cuenta propia o comprar una casa) son poco frecuentes y pueden entenderse tal vez como cambios coyunturales de prioridades, ligados a la situación crítica de la economía mexicana que privilegia las solidaridades familiares (uso más importante de las remesas para el sostenimiento de las familia en el lugar de origen) en detrimento de proyectos personales, a pesar

Cuadro 10

(N)	(72)	(71)	(56)	(190)	(389)	(288)	(100)

del contexto más favorable para la elaboración de estos últimos proyectos (subvaluación del Peso durante 1995).

Se observa en efecto, una brecha muy importante entre los proyectos definidos en el momento de la migración a Estados Unidos entre los que salieron durante los 3 últimos años (alrededor del 20% formulaban la compra futura de una casa como proyecto prioritario, y cerca del 8% proyectaban crear un negocio propio a su regreso a México), y los proyectos que desarrollan actualmente los migrantes que residen en el país vecino.

Actualmente, la duración de estancia en Estados Unidos no parece tener mucha influencia en la propensión a regresar al lugar de origen, contrariamente a lo que se podría pensar (cuadro 11). Si examinamos los proyectos actuales de los migrantes que residen desde hace 8 años y más en el otro país (la estancia promedio entre los ex-migrantes es de 7-8 años), observamos que más de la mitad de ellos (55%) piensan seguir trabajando en Estados Unidos por un tiempo indeterminado; cerca del 10% proyectan instalarse definitivamente allá, y 7% esperan jubilarse para volver a residir en México.

Los proyectos derivados de un eventual regreso a México (establecerse por cuenta propia, compra de casa), toman cierta importancia entre los migrantes que residen desde hace 4 o 7 años en Estados Unidos, es decir entre individuos que teóricamente, programarían actualmente su regreso definitivo a México durante los 2 o 3 próximos años. Sin embargo, se observa también en este grupo una débil propensión a elaborar un proyecto de regreso.

	100.0	100.0	100.0	100.0
(N)	(81)	(87)	(190)	(358)

El factor más importante en la elaboración de los proyectos actuales está relacionado con la situación familiar del migrante: su Estado Civil y sobre todo el lugar de residencia de la esposa cuando es casado.

Entre los migrantes casados cuyas esposas residen en Estados Unidos, cerca del 20% manifiestan el deseo de quedarse definitivamente a residir en este país. Esta proporción no pasa del 4% entre los solteros y los migrantes casados cuyas esposas residen en México. Es muy probable que la presencia de hijos nacidos en el país fronterizo en estas familias juega un papel importante en estas distribuciones. De la misma manera, cerca del 10% de los migrantes cuyas esposas residen en Estados Unidos esperan la jubilación para regresar definitivamente en sus lugares de origen, respecto al 3% máximo en los otros grupos (cuadro 12).

Todo parece indicar que una gran parte de los migrantes actuales están en situación de espera respecto a la evolución de la situación económica en México para definir un proyecto preciso y muchos de ellos están atrasando su regreso definitivo a sus lugares de origen.

Conclusiones

Aunque esta encuesta, en la cual se sustenta este trabajo, no fue diseñada para evaluar la evolución de la magnitud de los flujos anuales hacia Estados Unidos, se

puede conjeturar —con fuerte probabilidad— un incremento importante del flujo de emigración desde hace un año. Los principales indicadores (tasa de desempleo, índice de salario mínimo, relación tamaño de hogar/activos ocupados) de la economía mexicana que usamos aquí se deterioraron mucho desde 1994. Por otra parte, la economía norteamericana se encuentra desde hace 3 o 4 años en una fase de crecimiento relativamente sostenido que reactivó la demanda de trabajo y particularmente de mano de obra mexicana en muchas ramas de actividad. Esta reactivación —en desfase con la situación de la economía mexicana en 1995 y 1996— tuvo entre otras consecuencias, una casi duplicación desde 1993, de la relación de salarios promedios percibidos por los trabajadores mexicanos entre sus lugares de origen y los Estados Unidos, lo que volvió mucho más atractivo el desplazamiento hacia el país fronterizo desde el año pasado, a pesar de las dificultades crecientes que encuentran los migrantes al ingresar en ese país.

Esta situación de desfase en la evolución de las 2 economías creó pues un contexto muy favorable al desencadenamiento actual de una nueva ola migratoria, como ocurrió en los años 1983-1984 después del estallido de la crisis mexicana en 1982.

Los desplazamientos actuales movilizan migrantes primerizos (entre los cuales más y más jefes de familias al parecer), y también re-migrantes (componente de fuerte crecimiento en los flujos de salida desde fines de la década de los ochenta),

procedentes de la ola de regresos en México durante los primeros años de los noventa, y entre los cuales existe un fuerte potencial —como lo vimos— de nuevos desplazamientos en este contexto.

Además de la diversificación de las ramas de actividades de origen de los migrantes y de las ramas en las cuales se insertan en Estados Unidos, que tomó consistencia desde los años ochenta, se observa actualmente una diversificación de los Estados de destino de los flujos de salida hacia el país vecino. Esta redistribución geográfica es, en buena parte, una consecuencia del endurecimiento de la política que practican Estados como California respecto al fenómeno migratorio, y del deterioro del clima social (desarrollo de actitudes xenofóbicas por parte de varios sectores de la población norteamericana), pero se debe igualmente a la expansión tradicional de la migración jalisciense. Esto se manifiesta por una fuerte reducción de la parte de los flujos dirigidos hacia California, en provecho de otros Estados en el interior de la Unión Americana.

Por otra parte, los desplazamientos actuales parecen mucho más preparados, o menos aleatorios en cuanto a las condiciones de cruce de la frontera y a la inserción profesional en los lugares de destino. Esta inserción se produce más rápidamente no solamente gracias a una coyuntura económica favorable, sino también por la extensión y el buen funcionamiento de las redes de parientes y amigos que permiten asegurar a los migrantes la consecución rápida de un empleo al llegar a su destino.

Es probable igualmente que la diversificación de los lugares de destino, cuando se apoya en redes establecidas de conocidos, facilita la inserción de la población migrante en regiones y ramas de actividades menos concurridas o menos saturadas.

El fuerte incremento de los costos de desplazamiento (transporte, "pollero") no parece representar un freno al crecimiento del volumen de los flujos en la medida que los migrantes pueden solicitar con mayor frecuencia préstamos familiares en sus lugares de origen, que sustituyen en parte ahorros insuficientes, para financiar estos costos.

El incremento aparente de los salarios promedios percibidos por los migrantes en Estados Unidos desde hace unos años debería teóricamente favorecer los proyectos personales asociados a los regresos definitivos en México (creación de micro empresas o auto-empleo, compra de casa...) en la medida que los migrantes pueden asignar una fracción más importante de sus ahorros a estos proyectos. Sin embargo, a través de los proyectos actuales que planean los migrantes, no se perciben cambios significativos en este aspecto, tal vez porque la crisis económica en México se traduce por una mayor solicitud de recursos a los migrantes, y también porque muchos migrantes, al atrasar su regreso definitivo, esperan una estabilización de la situación económica o un mayor deslizamiento de la moneda mexicana frente al dólar. En este caso se "inflaría" momentáneamente el volumen de migrantes que residen en Estados Unidos actualmente.

Es probable que la paridad del Peso mexicano a mediados de 1996 (7.40 pesos/dólar) se ubica en su zona de equilibrio, pero el fuerte diferencial de inflación entre los dos países, que seguirá por lo menos durante los dos próximos años, puede dejar esperar para muchos, una nueva pérdida de valor de la moneda nacional que seguirá volviendo muy atractiva la migración hacia Estados Unidos.

Sin embargo, a mediano plazo (3-5 años), se puede considerar con cierto realismo una relativa estabilización de la paridad cambiaria, y la eliminación del desfase en la evolución de las dos economías, que borrará sensiblemente los altibajos coyunturales en la magnitud de los flujos migratorios anuales, y "desinflará" el volumen de la población migrante en Estados Unidos.

IMPACTS OF MIGRATION

The Participation of Mexican-born Households in Means-tested U.S. Welfare Programs

Paul S. Davies & Michael J. Greenwood

Introduction

Participation by the foreign born in welfare programs is the focus of considerable scrutiny in the United States. Presumably motivated by the notion that legal and unauthorized immigrants participate in some sense "too much" in such programs, Congress passed the Personal Responsibility and Work Opportunity Reconciliation Act of 1996. This Act restricts the access of even legal immigrants to welfare utilization. In spite of the passage of this legislation, many questions regarding immigrant utilization of public assistance programs remain only partially answered or unanswered. Precisely which public assistance programs are used relatively much by which entry cohort of which foreign-born group relative to which native-born group? The answers remain obscure. In this paper, we provide an unusually detailed analysis of public assistance utilization by Mexican-born households relative to various control groups of native-born households.

Dramatic changes in the number of immigrants entering the United States, in the source country composition, and in the age composition over the past 25 years have rekindled research interest and policy debate regarding the impact of immigrants on the U.S. economy. For example, what effects do immigrants have on U.S. factor markets, on the education system, and on the health care system? The research conducted here is focused in that it attempts to answer one specific question that stems from this recent immigration policy debate: Do Mexican immigrants use means-tested public programs more intensively than otherwise similar natives? The means-tested programs studied here are Aid to Families with Dependent Children (AFDC) and Supplemental Security Income (SSI). Social insurance programs constitute another type of public program. They refer to programs funded by payroll taxes on working individuals, primarily Social Security.[1] We account for Social Security income in this study, but we do not specifically study participation in the Social Security system.

Significant growth has occurred in immigrant welfare participation since 1970. As reported in Borjas and Trejo (1993), the percentage of households receiving welfare increased substantially for both native and immigrant households between 1970 and 1980. However, as shown in Table 1, the increase in the participation rate for immigrant households (5.9% in 1970 to 8.8% in 1980) was greater than that for native households (6.1% in 1970 to 7.9% in 1980). Table 1 also shows that the participation rate for immigrant households increased again to 9.1% in 1990, whereas that for native households actually decreased to 7.4%. Furthermore, female-headed households, whether native or immigrant, are more likely to receive welfare than male-headed households (Table 1).

Table 1
Percentage of Native and Foreign Born Households Receiving Welfare, 1970-1990

	All Households		Male-headed Households		Female-headed Households	
Year	Natives	Foreign Born	Natives	Foreign Born	Natives	Foreign Born

Source: Borjas and Trejo (1993) and Borjas (1994)

This paper makes two important advances in the analysis of participation in means-tested welfare programs by native-born and Mexican-born households. First, although several previous studies have empirically examined welfare participation by immigrants (e.g., Blau, 1984; Borjas and Trejo, 1991, 1993; Jensen, 1988; Tienda and Jensen, 1986; and Trejo, 1992), only Borjas and Trejo (1993) is based on an explicit, underlying theoretical model. In the section titled "Theoretical Model," a household utility maximization model is developed for the decision to participate in welfare (and social insurance) programs. Drawing from Moffitt (1981, 1983), welfare stigma is incorporated into the utility function and is allowed to vary across immigrant and native households. In the context of the theoretical model, private transfer income also is separated from other non-labor income because households receiving private transfers are likely to display different program participation patterns than households not receiving such transfers.

Second, a seven-equation simultaneous system is developed for empirical analysis that allows for explicit links between head and spouse hours worked, head and spouse wages, household consumption, and household welfare and social insurance participation. This model is more detailed than the models used in previous research and more accurately depicts the household decision-making process.

In the empirical work reported below we not only distinguish female-headed households and male-headed households, but we also separately identify single female-headed households. Single female-headed households have especially high AFDC participation rates. Moreover, within each type of household, we distinguish the age of the head (29 and under, 30-49, 50-64, and 65 and over). This last distinction allows for a better understanding of AFDC users, who tend to be relatively young, and SSI users, who tend to be somewhat older (primarily 65 and over). Finally, the types of models developed here study the foreign born relative to a control group of native-born persons. We consider four different native-born control groups (Mexican ancestry natives, all natives, white natives, and black natives). The various distinctions in the data in combination with the various control groups used in the analysis allow for a more complete understanding of welfare utilization of the foreign born.

The rest of this paper proceeds as follows: the following section, titled "Previous Findings," discusses the previous literature relating to welfare and social insurance participation by the foreign born. The next section lays out the theoretical model. The data set is discussed in the section titled "Data." The empirical model and estimation techniques are described in the section titled "The Model and Estimation Techniques." The next section presents the empirical results, and the final section provides a summary and conclusions.

Previous Findings

Several studies over the past 20 years examine the probability of social program participation by immigrants versus natives in the United States. However, none of these studies include all of the relevant explanatory variables (many times due to data availability problems), nor do they explore the link between hours worked and public program participation, as is done here. In general, previous studies show that immigrant households are less likely than otherwise comparable native households to participate in welfare programs, although the raw data indicate that immigrant households are more likely to participate than natives (Table 1). These studies typically focus on two variables: foreign-born status and year of entry. The foreign-born status variable is generally a simple dummy variable coded as one if the household head or spouse is foreign born and zero if native born. The year of entry variable is usually a series of dummy variables indicating when the head of the foreign-born household entered the U.S.; for example, head entered 0-5 years ago, 6-10 years ago, or head entered between 1975 and 1979 or between 1970 and 1974. These year of entry variables are usually interacted with the foreign-born status variable to examine immigrant participation differences across various entry cohorts. Certain studies, such as Borjas and Trejo (1991) and Jensen (1988), pool data from two U.S. Censuses. This procedure allows for the identification of cohort effects (by examining participation by different entry cohorts), assimilation effects (by examining the relationship between program participation and years since migration), and period effects (by examining participation differences due to being observed in the 1970 vs. 1980 Census), but not all three at once.[2]

A third variable, age at arrival, has rarely been included in empirical analyses of immigrant program participation, although its effect on program participation may be important. If immigrants arrive at younger ages, the majority of their human capital (education, experience, etc.) is accumulated in the U.S. Immigrants arriving at older ages, on the other hand, have little incentive to accumulate U.S.-specific human capital due to the shortness of their remaining work careers. Those immigrating at older ages may therefore place a greater burden on the SSI program, whereas those arriving at younger ages are more probable AFDC participants.

Blau (1984) is the only previous study that examines participation in both welfare and social insurance programs. Using the 1976 Survey of Income and Education, Blau conducts her analysis separately for male-and female-headed households. Focusing on six year of entry groups interacted with foreign-born status and controlling for various personal characteristics, Blau finds that foreign-born male-and female-headed families are initially significantly less likely to participate in both types of programs than are otherwise similar natives. Although length of time in the U.S. and probability of welfare recipiency do not display any consistent

pattern, Blau finds that the probability of immigrant participation in social insurance programs increases with time in the U.S. After residing in the U.S. for 16 (26) years, male (female) immigrants become significantly more likely to participate in social insurance programs than natives.

Borjas and Trejo (1991) pool the 1970 and 1980 Public Use Microdata Sample (PUMS) of the U.S. Census to examine immigrant welfare participation rates, allowing them to identify the cohort and assimilation effects on immigrant welfare usage. Among their findings, Borjas and Trejo (1991) report that more recent immigrant cohorts are more likely to enter the welfare system than are earlier cohorts (cohort effect) and that immigrant households are more likely to use welfare the longer they have been in the U.S. (assimilation effect). Borjas and Trejo also conclude that immigrant welfare participation rates have risen between 1970 and 1980, which is largely attributable to the shift in national origin mix of immigrants from European countries to Asian and Latin American countries. Finally, they calculate that the increased welfare participation of immigrants between the 1950-59 cohort and the 1975-80 cohort has increased welfare costs by over $5 billion.

Most studies account for the effect of Hispanic origin on the probability of program participation by including a dummy variable equal to one if the head is of Hispanic origin. Using such a strategy, Blau (1984), for example, finds that male-headed and female-headed Hispanic households are more likely to receive welfare, but less likely to receive social insurance, than are their otherwise similar non-Hispanic counterparts.[3]

Borjas and Trejo (1993) use the 1980 PUMS to compute unadjusted and adjusted welfare participation rates for 62 source countries for both male-and female-headed households.[4] For immigrants from Mexico, the male-headed participation rates are 8.7% (unadjusted) and 9.6% (adjusted) whereas the female-headed participation rates are 29.3% (unadjusted) and 22.2% (adjusted). By way of comparison, the mean participation rates for immigrants from all 62 countries are 5.1% (unadjusted) and 7.6% (adjusted) for male-headed households and 13.0% (unadjusted) and 16.6% (adjusted) for female-headed households. In all cases, immigrant households from Mexico are more likely welfare participants than are immigrants from all other countries on average.

Tienda and Jensen (1986) and Jensen (1988) analyze welfare participation differences between Hispanic immigrant households and native Hispanic households.[5] Both studies split the Hispanic group into Mexican, Puerto Rican, and other Hispanic households. Tienda and Jensen (1986) use the 1980 PUMS. Whereas the raw data indicate that immigrant Hispanic households are more likely to receive public assistance than native Hispanic households, the estimated model shows otherwise. Hispanic immigrant families are 9% less likely than otherwise

comparable natives to have received public assistance income in 1979. Within the Hispanic group, Mexicans are less likely, and Puerto Ricans more likely, to receive welfare payments than other Hispanics. Furthermore, recent Hispanic immigrants (those entering between 1975 and 1979) are 9% less likely to participate than otherwise similar Hispanic natives. Mexican families that immigrated between 1970 and 1980 are also less likely to participate in public assistance than are other Hispanic immigrant families or native families.

Jensen (1988) conducts essentially the same analysis as Tienda and Jensen (1986); however, he combines 1970 and 1980 Census (PUMS) data to examine differences in participation for each immigrant group both for different entry cohorts (e.g., 0-5 years ago, 6-10 years ago) and across the two time periods. Multivariate logistic regression analyses show that immigrants are generally less likely to use welfare than their native counterparts. Focusing on changes across the two time periods, he concludes that the lower likelihood of Hispanic immigrants using public assistance is specific to 1979. When Jensen (1988) beaks down immigrants by entry cohort, he further concludes that recent Hispanic immigrants in 1970 are more likely to participate, but Hispanic immigrants who entered 0 to 5 and 6 to 10 years ago in 1980 are significantly less likely to participate. Furthermore, recent Mexican immigrants are less likely to receive public assistance income.

Three important shortcomings are evident in nearly all of the studies discussed above. First, with the exception of Borjas and Trejo (1993), none of the studies base their empirical work on an underlying theoretical model. The Borjas-Trejo model, however, is significantly different than that developed in the following section titled "Theoretical Model." The authors model both the decision to immigrate to the U.S. and the decision to participate in a welfare program given immigration. As such, welfare participation becomes a function of source-country characteristics including income, income inequality, and distance from the U.S. (representing the cost of immigration). Participation in social insurance programs is not addressed, nor does the model allow for comparisons between otherwise similar immigrants and natives.

In the present paper, a utility maximization model is constructed following Moffitt (1983), which allows the family to explicitly choose participation or nonparticipation. Whereas the Moffitt model deals only with welfare program participation, the model employed here allows the family to separately choose to participate in welfare and social insurance programs. The model yields a system of equations for welfare program participation, social insurance participation, consumption, and labor supply.

Second, welfare stigma may play an important role in the participation decision, yet this issue is not covered in any previous studies. Moffitt (1981) incorporates stigma into a model of welfare participation by assuming that an individual receives disutility from participation in the AFDC program. Moffitt (1983) takes a

slightly different approach by allowing for a flat component of stigma, resulting from participation in and of itself, as well as for variable stigma, which is related to the size of the welfare benefit received. Given Moffitt's finding that stigma arises from participation and does not vary with the amount of the benefit given participation, the model employed in this paper incorporates only a flat component of stigma. Furthermore, stigma is associated with participation in welfare programs and not with participation in social insurance programs.

Third, private intra-family transfers may provide an important safety-net for families and may therefore influence both participation in and benefit levels received from welfare and social insurance programs. Although several studies (e.g., Cox and Jakubson, 1995; Schoeni, 1991) have examined the extent to which private transfers within families are crowded out by public transfer programs, none has addressed the reverse of this issue: To what extent, and in which direction, does the presence of private intra-family transfers influence the probability of participation in, and the level of payments received from, public transfer programs? For welfare programs, the effect is expected to be negative; however, the effect of private transfers on social insurance participation is more ambiguous.

Some descriptive statistics are illustrative of the importance of private transfers and the differences in private transfer behavior across countries of origin. Cox and Jakubson (1995) use 1979 survey data from the President's Commission on Pension Policy (PCPP). They find that private transfers make up about 10.3% of family income for those families receiving such transfers, while mean public transfers received for these families account for about 19.2% of family income (Cox and Jakubson, 1995, Table 1). In the PCPP survey, 25.9% of the families reported receiving private transfers within the sample time interval. Unfortunately, this sample relates to a very small number of families (4,232 family units were included) and does not make any distinction as to the foreign-born or native-born status of the families surveyed.

In a review article, Cox and Jimenez (1990) present descriptive statistics relating to private transfers in other countries. Private transfers are more prevalent and make up a larger share of total family income in other countries than in the U.S. For example, in rural India, 93% of households reported receiving some form of private transfer, with the average transfer amount accounting for 11% of household income. In Malaysia, between 19% and 30% of households received a private transfer. Here the average transfer amount accounted for 11% of household income. The comparable figures reported for the United States are 15% of households receiving private transfers, making up 1% of household income on average (Cox and Jimenez, 1990, Table 1).

Although the statistics presented above are quite general, they support two claims. First, private intra-family transfers are received by a significant number of

households in both the United States and other countries. If the hypothesis that private transfers affect the propensity to use public transfer programs is correct, then excluding private transfers from the model would be a serious omission. Second, the observed differences in private transfer patterns across countries lend support to the argument that immigrants from various countries may behave differently than natives with respect to public program participation. These differences may stem from cultural differences and therefore would not be detected by simply holding constant such characteristics as age and education.

Only two previous studies, Tienda and Jensen (1986) and Jensen (1988), attempt to control for private transfers. Both do so by including a dummy variable for extended family status as an explanatory variable in the welfare program participation equations. The hypothesis is that extended families are more likely to provide informal support within the family and should therefore exhibit lower propensities to participate in welfare programs, all else equal. Indeed, Wolpin (1980) demonstrates that immigrant families, especially Mexicans and Asians, are more likely to reside in non-nuclear households. However, Tienda and Jensen (1986) and Jensen (1988) both find that extended family status increases the probability of welfare participation. This proxy for the actual presence and amount of private intra-family transfers is clearly not satisfactory, but more satisfactory measures are rarely available in the data.

In this study, private transfers directly enter the utility maximization model as a form of non-labor income in the budget constraint and carry through to become an argument in the demand equations for welfare and social insurance participation. Private transfers should therefore enter the empirical model, although data availability presents a significant constraint here. This issue is discussed further in the section titled "Data."

The results obtained in a number of previous studies are sensitive to the control group of native-born persons that is chosen as the comparison group for the foreign born (Greenwood and McDowell, 1986). For example, a common control group is otherwise comparable native-born persons of the same ancestry as the foreign-born group (e.g., Davies, 1996). However, other control groups also are meaningful to study, such as all native-born persons, white native-born persons, black native-born persons, and even other foreign-born groups. In this study, we examine persons born in Mexico relative to a number of alternative control groups.

Census data on welfare participation do not distinguish the precise program in which the individual or household participated. Thus, Aid to Families with Dependent Children (AFDC) and Supplemental Security Income (SSI) are bundled together in "welfare income." This aggregation is problematic because the two types of programs mainly are used by different types of individuals. For example, AFDC utilization is oriented toward single-parent, female-headed households, whereas

SSI is oriented toward aged persons and the disabled. During 1990 and 1991, of SSI recipients who were lawful resident aliens, almost 65 percent were aged whereas about 35 percent were blind or disabled. A better understanding of participation in means-tested welfare programs by the foreign born thus requires considerable disaggregation of the population. In this study, we distinguish various age groups, and we also specifically identify single-parent households.

Theoretical Model

The model presented below examines the separate decisions of households to participate in welfare programs and social insurance programs. This is a micro-oriented approach to the problem, as opposed to the more macro-oriented model of Borjas and Trejo (1993), and appropriately places the participation decision at the household level, rather than at the individual level. Allowing the household to separately choose welfare and social insurance participation within a single utility maximizing framework represents a significant advance over previous theoretical work in this area.

Furthermore, drawing from Moffitt (1981, 1983), the model incorporates welfare stigma into the utility function and includes a parameter that allows stigma to vary across immigrant and native groups. The foreign-born and native-born may respond differently to the stigma of welfare participation, due to unobservable cultural differences.

Moreover, the model developed here separates private transfer income from other non-labor income, because households receiving such private transfers are presumably less likely to participate in welfare and social insurance programs than otherwise similar households not receiving private transfers. As with welfare stigma, this response is expected to differ between natives and the foreign born. Several papers (e.g., Cox and Jakubson, 1995; Schoeni, 1991) have examined the relationship between private and public transfers. However, these papers are primarily concerned with the crowding out effects of public transfers on private transfers. The effect of private transfers on the propensity to participate in public transfer programs is not examined, nor are differences in such relationships between immigrants and natives explored. Our model remedies these shortcomings.

Our model presented is based on a model developed by Moffitt (1983). However, several modifications make it more amenable to foreign born-native born comparisons of program participation. In Moffitt (1983), the unit of analysis is the individual and the decision of interest is participation or non-participation in a welfare program (namely, AFDC). Because the model presented in this paper is applied to participation in both welfare and social insurance programs, it is more appropriate that the household be the unit of analysis. Specifically, household utility

is specified as a function of consumption by each member of the household, c_i, and labor supply of each member, h_i, where I=1,...,n. The household head is assumed to be the decision maker. The general form of this utility function is

$$(1)\quad U = u(c_1,...,c_n,h_1,...,h_n) - \lambda\phi A_2.$$

Each member's consumption c_i can be thought of as a vector of goods with associated price vectors p_i. Alternatively, each c_i may be considered an individual specific composite commodity with price p_i. The utility function is assumed to be concave.

A distinguishing feature of this utility function is the ($-\phi A_2$) term representing welfare stigma. A_2 is a dichotomous variable equal to 1 if the household participates in a welfare program and equal to 0 if the household does not participate. The stigma parameter ϕ indicates the reduction of utility due to participation in a welfare program. Moffitt (1983) also includes such a term, defined as the flat component of stigma. A variable component of stigma is included by Moffitt (1983) as well, allowing stigma to change with the level of welfare benefits received. However, Moffitt finds this variable component to be insignificant; hence, it is not included in the model developed here.

No stigma is associated with participation in a social insurance program. Participation in such programs is in some sense a right (entitlement) people acquire as a result of tax contributions throughout their working years, whereas welfare program participation many times signifies the inability of a person or family to provide for themselves. The λ parameter attached to ($-\lambda\phi A_2$) is an adjustment parameter allowing the effects of stigma from welfare participation to vary across immigrant and native households. Here, λ will be greater than, equal to, or less than one depending upon whether immigrants attach more, the same, or less stigma, respectively, to participation than natives. For native households, λ is equal to one.

The budget constraint facing the household simply equates expenditures on consumption goods by each member of the household to full household income

$$(2)\quad \sum_{i=1}^{n} p_i c_i = \sum_{i=1}^{n} w_i h_i + N + X + A_1 T + A_2 B,$$

where w_i is member I's wage, N is total household non-labor income, and X is total household private transfer income. Household income from social insurance programs is taken into account by the A_1T term where A_1 is a dichotomous variable equal to 1 if the household receives social insurance benefits and equal to 0 if the household does not receive such benefits. T is the household's benefit from social

insurance programs. Household welfare income enters the budget constraint as A_2B, where A_2 is the dichotomous welfare participation variable and B is the household's welfare benefit.

As noted above, private transfer income is included in the model because households receiving private transfers presumably are less likely to participate in welfare and perhaps social insurance programs. Total private transfers may be defined as $X = X_1 + X_2$, where X_1 denotes private transfers within the household and X_2 is private transfers from other households. A household's participation in a welfare or social insurance program may be influenced more by private transfers from other households than by those within the household. Private transfers within the household do not alter the total resources available to the household, but simply redistribute these resources. Therefore, within-household private transfers should have little effect, if any, on a household's participation in welfare and social insurance programs.

Given that welfare programs are means-tested, providing an income guarantee $\overline{G}$ and taxing earned income at rate t, an additional constraint, defining the welfare program benefit level, must accompany the budget constraint

$$(3) \quad B = \overline{G} - t\sum_{i=1}^{n} w_i h_i.$$

The income guarantee, $\overline{G}$, and the program tax rate, t, are expected to be important variables for the empirical analysis because they can vary greatly by state for welfare programs such as AFDC. For example, state AFDC benefit guarantee levels for a family of two (one adult and one child) in 1989 ranged from a low of $88 per month in Alabama to a high of $752 per month in Alaska, with a mean of $313. The nominal program tax rate is currently set by federal statute at 100%. In other words, AFDC benefits are reduced by $1 for every $1 of earned income (beyond some minimal excludable amount for work-related transportation expenses). However, the effective AFDC program tax rate is much lower and varies greatly by state. Fraker, Moffitt, and Wolf (1985) estimate these effective tax rates over the period 1967 to 1982. In 1979, for example, the effective AFDC tax rate ranged from a low of 13% in Georgia, Mississippi, and South Carolina, to a high of 55% in Illinois, with a mean of 29%. The effective tax rate is the more relevant measure for the empirical analysis because it accounts for income and asset exclusions allowed for under AFDC rules. However, measures of the effective tax rate for 1989 may not be available and may be difficult to estimate due to data limitations. This issue is discussed further in the section titled "Data."

The household's problem is then to maximize (1) subject to (2) and (3). Given that A_1 and A_2 are dichotomous variables (i.e., participate or do not participate), the household can be thought of as first maximizing utility (1) by choosing c_i and h_i for

all I=1,...,n holding A_1 and A_2 constant. A_1 and A_2 are then chosen to maximize (indirect) utility through some combination of participation and non-participation. Solution of the first-order conditions yields a consumption demand equation and a labor supply equation for each household member I. These are standard Marshallian demands with arguments including individual specific prices, (net) wages and family income from sources other than labor:

(4a)
$$h_i = h_i^*(p_1,...,p_n, w_1(1-A_2t),...,w_n(1-A_2t), N + X + A_1T + A_2\overline{G}) \quad \forall i,$$

and

(4b)
$$c_i = c_i^*(p_1,...,p_n, w_1(1-A_2t),...,w_n(1-A_2t), N + X + A_1T + A_2\overline{G}) \quad \forall i.$$

A feature of these demand equations is that the price and wage facing each individual household member is an argument in member I's consumption demand and labor supply functions, which adds some notion of interdependence between household members in making consumption and labor supply decisions.

Substituting (4a) and (4b) into the utility function (1) produces the indirect utility function, given A_1 and A_2

(5)
$$V(p_1,...,p_n, w_1(1-A_2t),...,w_n(1-A_2t), N + X + A_1T + A_2\overline{G}; A_1, A_2)$$
$$= u(c_1^*,...,c_n^*, h_1^*,...,h_n^*) - \lambda\phi A_2.$$

The stigma term ($-\lambda\phi A_2$), which is allowed to vary across immigrant and native groups, is incorporated into the indirect utility function, although it does not appear in the demand equations (4a) and (4b). The object is now for the household head to simultaneously determine social insurance participation (A_1) and welfare participation (A_2) in order to "maximize" household indirect utility.

An important issue to be considered here is that of eligibility for the welfare and social insurance programs under consideration. As discussed by Moffitt (1983), eligibility for the means-tested welfare programs is included in the model by virtue of the benefit level equation (3) and the welfare stigma term ($-\lambda\phi A_2$). Some households may not participate because income is too high to generate a positive benefit level. Others may be eligible based on income, but may choose not to participate due to the reduction of utility through welfare stigma. Eligibility for social insurance programs is a bit more difficult to deal with. In the case of Social Security, for

example, quarters of covered employment and age are the primary determinants of a household's eligibility. Those households not meeting the minimum eligibility requirements may be thought of as facing an additional constraint, eliminating the choice of $A_1 = 1$.

The household head maximizes indirect utility by choosing the combination of A_1 and A_2 that yields the greatest indirect utility. More formally, two threshold functions, A_1^* and A_2^*, are created to represent the demand for participation in each type of program:

(6a)
$$A_1^* = V(p_1,...,p_n, w_1(1-A_2t),...,w_n(1-A_2t), N + X + T + A_2\overline{G}; 1, A_2)$$

$$-V(p_1,...,p_n, w_1(1-A_2t),...,w_n(1-A_2t), N + X + A_2\overline{G}; 0, A_2);$$

and

(6b) $$A_2^* = V(p_1,...,p_n, w_1(1-t),...,w_n(1-t), N + X + A_1T + \overline{G}; A_1, 1)$$

$$- V(p_1,...,p_n, w_1,...,w_n, N + X + A_1T; +A_1 0).$$

If the household head compares indirect utility with participation to indirect utility without participation, the decision rule for each program becomes:

(7a) $A_1 =$
$$\begin{cases} 1 \text{ if } A_1^* > 0 \text{ (participate)} \\ 0 \text{ if } A_1^* \leq 0 \text{ (do not participate);} \end{cases}$$

7b) $A_2 =$
$$\begin{cases} 1 \text{ if } A_2^* > 0 \text{ (participate)} \\ 0 \text{ if } A_2^* \leq 0 \text{ (do not participate).} \end{cases}$$

The choice of participation or non-participation essentially comes down to the question of whether the additional utility received from additional income given participation outweighs the stigma associated with participation. If the utility gain from participation is greater than the utility loss from stigma, then the household participates. If not, it does not participate. The participation decision is a single decision made by the household head on behalf of the entire household. This formulation of the stigma term allows for differing participation behavior across immigrant and native households.

Equations (4a), (4b), (7a), and (7b) can all be combined to form a system of demand equations for estimation purposes.

Demand for social insurance program participation:

$$A_1 = \begin{cases} 1 \text{ if } A_1^* > 0 \\ 0 \text{ if } A_1^* \le 0 \end{cases} \quad \text{where } A_1^* \text{ is given by (6a)}$$

Demand for welfare program participation:

$$(8)\quad A_2 = \begin{cases} 1 \text{ if } A_2^* > 0 \\ 0 \text{ if } A_2^* \le 0 \end{cases} \quad \text{where } A_2^* \text{ is given by (6b)}$$

Demand for consumption:

$$c_i = c_i^*(p_1,...,p_1, w_1(1-A_2t),...,w_1(1-A_2t), N + X + A_1T + A_2\overline{G}) \quad \forall i$$

Labor supply:

$$h_i = h_i^*(p_1,...,p_1, w_1(1-A_2t),...,w_1(1-A_2t), N + X + A_1T + A_2\overline{G}) \quad \forall i.$$

The system (8) is used as the basis of the empirical model of the section titled "The Model and Estimation Techniques."

Data

The data set employed for the empirical analysis is the 5% sample of the 1990 Public Use Microdata Sample (PUMS) of the United States Census (Bureau of the Census, 1992a). This data set contains both household records and person records for the individuals comprising each household. For the entire country, several million observations are available on over 200 different variables. Of particular interest for this study are the geographic identifier variables on the household record and the relationship, place of birth, year of immigration, and income variables on the person records. The geographic identifier variables are important in that they allow identification of the state and the metropolitan statistical area (MSA) in which each household resides. Thus, differences in welfare eligibility rules and benefit payments across states can be taken into account, as can differences in participation behavior in metropolitan and nonmetropolitan areas.

The place of birth and year of immigration variables are clearly of central importance to this study. The sample is designed to include foreign-born households from Mexico and native-born households of Mexican ancestry, as well as various other native-born households. The year of entry variable allows for the identification of eight different year of entry categories for the foreign-born population. These categories are as follows: 1985-90, 1980-84, 1975-79, 1970-74, 1965-69, 1960-64, 1950-59, and before 1950. Use of these year of entry variables is important for several aspects of this study.

Most previous studies have counted as foreign born only those households with a foreign-born head, ignoring the place of birth of the spouse. In this study, we classify as foreign born all households in which either the head or the spouse (if present) was born in another country. This classification method results in more complete coverage of the foreign-born population.

Finally, the income variables are of great importance. For each individual, eight sources of income are identified in the PUMS: wage and salary income; nonfarm self-employment income; farm self-employment income; interest, dividends, and net rental income; social security income; public assistance income; retirement income; and all other income. Each income measure refers to income of that type received in 1989. Public assistance income is the key measure for this study. As noted above, public assistance income includes income from both Aid to Families with Dependent Children (AFDC) and Supplemental Security Income (SSI). A household is classified as a public assistance program participant if it had positive income from the public assistance programs. Because separate measures of AFDC and SSI are not available, we distinguish the groups most likely to receive each by age and other characteristics.

The analysis conducted in this study is a household-level analysis. Individual income measures are combined to yield, at the household level, measures of earned income, nonearned income, social security income, and public assistance income. Several of the individual-level characteristics are preserved, however. Education levels and head and spouse income measures are maintained at the person level for use in estimated wage and hours worked equations.

With aggregation of individual characteristics to the household level, an issue arises concerning which member's characteristics to use for such household characteristics as ancestry, place of birth, and year of entry. The procedure adopted here is to use the characteristics of the head. For example, household ancestry for native-born households is determined by the ancestry of the household head. The foreign-born characteristics such as place of birth and year of entry are determined by the relevant characteristics of the individual conferring foreign-born status on the household. If the head is the foreign-born member, the household's place of birth and year of entry are those of the head. If the household head is native-born,

but the spouse is foreign-born , then the spouse confers foreign-born status on the household and the household's place of birth and year of entry are those of the spouse. Individual-level ancestry, place of birth, and year-of-entry variables also are maintained for the head and the spouse. These are important variables for the estimated wage and hours worked equations. No attempt is made to create a household education-level variable, because this and other characteristics like it are specific to individuals and are maintained as such in the data.

Households with no persons residing in them (presumably vacant households) and households with negative values for any of the income measures are trimmed from the sample, as are institutional units such as prisons, nursing homes, retirement homes, and mental institutions. Households with either the head or the spouse on active military duty also are deleted from the sample because active duty military personnel participate in a different human capital accumulation process than does the non-military population, and are therefore likely to behave differently with respect to program participation. A variable does, however, identify military veterans. This dummy variable is included as an independent variable in all estimated equations to control for any potential behavioral and/or human capital differences of those who have served in the military.

Another important data-related issue has to do with the use of sample weights. Data from the 1980 PUMS are self-weighted, which implies that the sample was a random sample of the entire population. However, the 1990 PUMS contains two different types of weights, a household weight and a person weight. Each household is assigned a unique household weight and each person within each household is also assigned a unique person weight. According to the PUMS documentation, these weights are to be applied when analyzing the data so that estimates can be taken to be nationally representative. In other words, the 1990 PUMS is not a random sample. The weights are designed to correct for over-sampling of certain groups and under-sampling of other groups.

If the analysis utilized only household records, the household weight would be the appropriate choice. Likewise, the person weight would be appropriate if only person records were being analyzed. However, this analysis makes use of both household variables and person variables, some of which have been combined to create household-level characteristics. Given this information, neither the person weights nor the household weights are used in any part of the analysis. This is done for two primary reasons. First, no aggregating is done beyond the household level, so weighting does not seem appropriate. Second, and perhaps more important, the sample properties upon which the household and person weights were derived are in some sense destroyed in the process of eliminating households as described above. Because, for example, individuals on active military duty were deleted, person-weighted estimates will be no more "nationally representative" than the

unweighted estimates. All regression results and descriptive statistics presented below are based on the raw, unweighted data and therefore represent the actual contents of the PUMS data set created and used here.[6]

Several variables necessary for the analysis are constructed from the raw Census data, including years of education, potential labor market experience, the log of head and spouse wages, and head and spouse hours worked. Each of these is briefly discussed in the following paragraphs. For years of education, the 1990 PUMS provides a variable called YEARSCH which has 17 education categories ranging from no completed years of school to doctorate degree. However, the coding of this variable does not allow it to be used as a continuous measure of educational attainment. We therefore assigned a number to each category to represent the number of years of education necessary to reach that level. For example, the category "Bachelor's degree" was assigned 16 years of education. In this way, we created a continuous educational attainment variable called EDUC that is used in several of the estimated equations.[7] The variable EDUC is then used to create a measure of potential labor market experience, EXPER, as typically used in Mincer earnings equations. EXPER is computed as age less education less six.[8] The experience variable also is used in the estimated wage equations.

Head and spouse hours worked and the logarithm of head and spouse wages also are created. Hours worked are defined as the product of number of weeks worked in 1989 and average hours worked per week in 1989, which results in the variables HHOURS for household heads and SHOURS for spouses. Although this is a somewhat imperfect measure of hours worked, it is the best that is available in the 1990 PUMS. The wage is created by dividing wage and salary income in 1989 by HHOURS for household heads and by SHOURS for spouses. The logarithm of the wage is then taken to create head's log wage, LHWAGE, and spouse's log wage, LSWAGE. Various descriptive statistics are reported in Appendix 2.

One final issue to discuss here is that of private transfer income. Private transfer income is referred to in the section titled "Previous Findings" as an important explanatory variable that has been excluded from all previous studies and is included in the theoretical model of the section titled "Theoretical Model." Due to the limitations of the Census data, we are unable to compute a reasonable measure for this variable. Therefore, household private transfer income is excluded from the empirical work of this study.[9]

The Model and Estimation Techniques

The empirical model is derived based on the demand equations from the theoretical model presented above. However, a number of changes were made due to shortcomings of the data set. First, private transfers are not separated from

nonearned income as is done in the theoretical model since no measure of private transfers is available in the 1990 PUMS. Presumably, private transfers received from other family members are included in the "All Other Income" component of nonearned income.

Two other compromises from the theoretical equations are made for the purpose of empirical tractability. Whereas the theoretical model calls for the estimation of a labor supply equation and a consumption equation for each member of the household, the empirical model estimates a labor supply equation only for the household head and spouse (if present) and a single household-level consumption equation. The closest measure of consumption available is gross rent (for renters) and selected monthly owner costs (for owner-occupied homes, condominiums, and mobile homes). These cover primarily rent, mortgage payments, utilities, and insurance (Bureau of the Census, 1992b). These measures are transformed into a measure of annual spending for each household. Admittedly, several problems arise in measuring consumption in this way, perhaps the most important of which is the investment-like features of housing and housing services expenditures. Unfortunately, it is the best measure available in the 1990 PUMS.

The empirical model consists of seven equations for each household: head hours worked, spouse hours worked, head wage, spouse wage, social security participation, public assistance participation, and household consumption. The complete empirical model is as follows:

$$(9)\quad hhours = \beta_0 + \beta_1 sspart + \beta_2 pastpart + \beta_3 shours + \beta_4 lhwage + x_1\psi_1 + \varepsilon_1$$

$$(10)\quad shours = \gamma_0 + \gamma_1 sspart + \gamma_2 pastpart + \gamma_3 hhours + \gamma_4 lswage + x_2\psi_2 + \varepsilon_2$$

$$(11)\quad lhwage \mid (hhours > 0) = \delta_0 + x_3\psi_3 + \delta_1 hmills + \varepsilon_3$$

$$(12)\quad lswage \mid (shours > 0) = \eta_0 + x_4\psi_4 + \eta_1 smills + \varepsilon_4$$

$$(13)\quad sspart = \theta_0 + \theta_1 lhwage + \theta_2 lswage + \theta_3 pastpart + x_5\psi_5 + \varepsilon_5$$

$$(14)\quad pastpart = \pi_0 + \pi_1 lhwage + \pi_2 lswage + \pi_3 sspart + x_6\psi_6 + \varepsilon_6$$

$$(15)\quad yspend = \mu_0 + \mu_1 lhwage + \mu_2 lswage + \mu_3 sspart + \mu_4 pastpart + x_7\psi_7 + \varepsilon_7$$

where the variables are defined in Appendix 1. The vectors x_1 through x_7 are vectors of exogenous explanatory variables which may contain common elements. These explanatory variables include household head characteristics, other household characteristics, area characteristics, and foreign-born characteristics in order to ensure the comparison of "otherwise similar households."

The model is simultaneous due to the appearance of endogenous explanatory variables in the labor supply, program participation, and consumption equations. Given this simultaneity, the system must be identified so that meaningful estimates of the coefficients may be obtained. In order to ensure identification, the rank and order conditions are checked (Kmenta, 1986). The system passes both conditions for identification and can therefore be estimated by any appropriate systems estimation technique.

The estimation technique adopted here is a two-stage procedure. In the first stage, reduced-form equations are estimated for all right-hand-side endogenous variables (i.e., hhours, shours, sspart, and pastpart). These reduced-form equations cannot be estimated by ordinary least squares due to the nature of the dependent variables. Head and spouse hours, for example, are left censored at zero due to the presence of non-working heads and spouses in the sample. Tobit is the appropriate estimation method for the head and spouse hours worked equations. The program participation variables, on the other hand, are dichotomous variables equal to one if the household participates and zero otherwise. With this type of dependent variable, probit is the appropriate estimation technique. The fitted values from these reduced-form equations are retained and renamed by adding the extension "ht" to the variable name.

As part of the first stage, the log-wage equations are estimated for the subsamples of working heads and spouses. The estimated wage equations are run separately for the household head and spouse (if present). Those who did not work in 1989 are initially assigned a wage of zero. However, this cannot be used as their wage in estimating equations (9) through (15) above. As described in the labor supply literature, a wage of zero does not imply that the individual has no market earnings. It means that the wage that individual could command in the labor market, given his or her skills and ability, is less than that individual's reservation wage. This being the case, the individual chooses not to work. For purposes of estimating the model above, a predicted wage must be derived for the subsample of non-working heads and spouses based on his or her human capital and socioeconomic characteristics.

The estimated wage equations take a standard form, including sex, potential market experience and its square, education, work limitation status, ability to speak English, and a vector of foreign-born status indicators as independent variables.[10] The wage equation is run for the subsample of working heads or spouses, including

the inverse Mill's ratio as a correction for sample selection bias. The inverse Mill's ratio is derived from Tobit estimates of the parameters from the head (spouse) hours worked equation. Inserting this inverse Mill's ratio (sometimes called Heckman's lambda) into the estimated wage equation has become a standard method of correcting for sample selection bias.[11] The estimated parameters are applied to the characteristics of the full sample of heads (spouses), both working and not working, to arrive at a predicted or estimated wage for each head (spouse) in the sample. When no spouse is present in the household, the spouse's estimated wage is set equal to zero. The variables LHWAGEHT and LSWAGEHT refer to predicted head and spouse log wages, respectively.

The second stage involves estimating the structural equations of the model (equations 9, 10, 13, 14, and 15) using the first stage fitted values in place of the right-hand-side endogenous variables. The structural equations for head and spouse hours are estimated by Tobit while those for social security and public assistance participation are estimated by Probit. Household consumption is estimated by ordinary least squares (OLS).

A variable is included in the analysis to control for age at entry into the U.S. This variable is constructed as current age less the midpoint of the year group in which entry occurred. For natives, age at entry is set equal to zero. Friedberg (1993), in the context of immigrant labor market assimilation, shows that age at arrival is an important explanatory variable, though it has been excluded from nearly all previous studies. She finds that immigrants arriving at older ages earn less at every stage of assimilation than otherwise similar immigrants arriving at younger ages. Furthermore, controlling for age at arrival reduces the rate at which immigrants close the earnings gap with otherwise similar natives.

In the case of welfare participation, age at arrival may play a similarly important role. For example, foreign-born persons arriving while young may gain greater knowledge of the U.S. welfare system and may therefore be more likely participants than otherwise similar foreign-born persons arriving at older ages. Furthermore, those arriving earlier in their lives may lose the feelings of stigma attached to welfare participation in their home country as they grow up more like Americans. If this is the case, welfare participation and age at arrival will be negatively related. On the other hand, foreign-born persons arriving at younger ages may have made greater earnings progress through the assimilation process than otherwise similar foreign-born persons arriving later in life and may therefore be less likely to participate in welfare programs. These hypotheses are empirically tested below.

Friedberg (1993) also points out an important identification issue when including age at arrival as an explanatory variable. For the foreign born, current age is equal to years since arrival plus age at entry. Including all three explanatory

variables in the same equation leads to perfect colinearity and the parameters are not identified. However, by including both foreign born and natives in the sample, identification of these three parameters is possible because the relation "current age equals years since arrival plus age at entry" does not hold for natives. Friedberg (1993) correctly argues that if one imposes the restriction that the effects of current age on participation are the same for the foreign born and natives, then the parameters on current age, years since arrival, and age at entry can all be identified. This identification method is employed here, although it imposes no true restriction on the model since foreign-born and native households are to be pooled, and a single coefficient is estimated for the current age variable, regardless of the inclusion of the age at entry variable. A simple addition, including the age at entry variable represents an important advance over previous studies of welfare program participation by the foreign born.

Empirical Results

In the results reported below, several types of households are studied: (1) all households; (2) all households, by age (49 or less, 50-64, 65 or over); (3) all female-headed households; (4) all female-headed households, by age (29 or less, 30-49, 50-64, 65 and over); (5) single female-headed households; (6) single female-headed households, by age (29 or less, 30-49, 50-64, 65 and over); (7) male-headed households; (8) male-headed households, by age (29 or less, 30-49, 50-64, 65 and over). For all households, two sorts of models are reported. The first is a "country model" that contains a dummy variable distinguishing household heads (or spouses) born in Mexico. The second is a "country/entry cohort model" that contains a set of dummy variables for Mexican-born household heads indicating the period of their U.S. entry (1985-90, 1980-84, etc.). For other household types, only the country/entry cohort model is reported. The country/entry cohort model provides more detail about the participation behavior of Mexican-born households relative to native-born households. Moreover, four different control groups of native-born households are used: (1) Mexican ancestry natives; (2) all natives[12]; (3) black-headed natives; (4) white-headed natives. The various control groups are used selectively.

The sample splits we have made are motivated by drastic differences in welfare participation rates across the groups as presented in Table 2. For example, female-headed households display participation rates that are more than double those for male-headed households. This difference is even more pronounced for single female-headed households. Although male-headed households tend to have relatively low participation rates, these households are examined due to their large sample sizes relative to female-headed households. Participation rates for the Mexican born and

Source: Authors' computations from 1990 PUMS. Number of households in each group in parentheses.

for Mexican ancestry natives typically increase from the young to the old, suggesting that SSI usage is quite high among these groups. This pattern is not as strong for the group of all native households.

In the discussion below, we focus primarily on the dummy variable for Mexico (country model) and the set of dummy variables indicating entry cohort (country/entry cohort model). Other variables are discussed selectively. All Probit coefficients reported below have been transformed following Green (1997) so that they may be interpreted as marginal effects.

All Households

Table 3 indicates that households headed by Mexican-born persons are only slightly more likely to participate in welfare than otherwise comparable households headed by native-born persons of Mexican ancestry. Furthermore, they are no more likely to participate than households headed by native-born persons in general. However, they are more likely to participate than native white households, but are less likely to participate than native black households.

Several variables in the models are included to control for eligibility to receive welfare. Among these are the number of household members 17 years old or younger (SHHLE17), the number 65 years old or older (SHHGE65), and the number disabled (SHHDISAB). Each of these variables has been interacted with the MEXICO dummy variable. Relative to each control group, Mexican-born households are more likely to receive welfare, presumably SSI, if they contain persons 65 and over, but they are less likely to receive it (presumably AFDC) if they contain persons 17 or younger. Moreover, they are less likely to receive welfare if the household has a disabled person or persons in it.

The models also include three variables that reflect characteristics of the place of residence: the state's average monthly AFDC payment (AFDCAVG), the state's average SSI payment (SSIAVG), and residence in a metropolitan area (INMA). Relative to all native households and to white-headed native households, Mexican-born households are more likely to receive SSI in states that provide supplements to this national program. Relative to native households of Mexican ancestry and to white-headed native households, they are also more likely to receive AFDC if they reside in states with relatively generous AFDC benefits.

The country/entry cohort models reported in Table 4 provide a more precise depiction of welfare usage by Mexican-born households. Relative to each control group, Mexican-born households are significantly less likely to participate in welfare if they entered the United States more or less recently, which is to say between 1970 and 1990. Because persons are most likely to migrate during their childbearing years, this empirical result suggests that Mexican-born households are less

likely to participate in AFDC than the various native-born households, which is a finding further supported by evidence reported below.

More distant Mexican-born cohorts are more likely to receive welfare than most of their native-born counterparts, except blacks. For example, those who migrated between 1950 and 1964 are significantly more likely to participate than otherwise comparable native-born households of Mexican ancestry. Relative to white-headed native households, the same is true for those who entered the United States in 1964 or earlier. The participation of these very distant entry cohorts is almost certainly in the SSI program.

Certain other results are also of some importance. For example, in both the country model and the country/entry cohort model, and relative to all four native control groups, household heads with higher education levels are significantly less likely to participate. The same effect is evident for spouse education. Furthermore, household heads who are widows or widowers are significantly less likely to participate in all cases. Finally, households with an unemployed head or spouse are significantly more likely to receive welfare payments.

For all households, Tables 5 and 6 distinguish three age groups (49 or less, 50-64, 65 or over). The idea behind this distinction is to better identify those groups that are most likely to participate in AFDC (49 or less) and those that are most likely to participate in SSI (65 or over). The tables contain only the country/entry cohort models, and they report findings for two control groups—Mexican ancestry natives (Table 5) and all natives (Table 6).

For the group less than 50 years old, only the most recent entry cohort from Mexico (entered 1985-90) is significantly less likely to participate in welfare than native-born households of Mexican ancestry. Those who entered before 1970 are more likely to participate. The results are similar when all natives form the control group. Mexican-born households in this age class with persons 65 or over are less likely to use welfare than Mexican ancestry natives but more likely to use it than native whites. Relative to both control groups, Mexican-born households with persons 17 or under and with disabled persons are less likely to participate.

For the group 50 to 64 years of age, no statistically significant differences are evident for any entry cohort relative to Mexican ancestry natives. However, relative to all natives, more distant entry cohorts (especially those before 1970) are more likely to participate. Results for the 65 or over age class are similar for recent entry cohorts, except that the foreign-born group is marginally more likely to use welfare than each control group. For more distant entry cohorts, the Mexican-born group is no more likely to participate than all natives.

Where AFDC payments are relatively high, the youngest age group is more likely to participate in welfare, and where SSI payments are generous the oldest group is more likely to participate. This pattern is consistent with the eligibility

requirements for participation in each program. As for the results presented above for all households, higher educational attainment by the household head reduces the probability of participation for households in all three age groups. Head and spouse unemployment status are positively related to participation in welfare programs, and this result also is consistent across age groups.

Female-headed Households

The incidence of AFDC usage is far higher among female-headed households than among male-headed households. This is clearly evident in Table 2, which indicates that the 1990 welfare participation rate for native female-headed households is 13.5%. That for native, single female-headed households is 14.3%, and for native male-headed households is 4.6%. Comparable figures for Mexican-born households are 24.2% (female-headed), 28.0% (single female-headed), and 8.7% (male-headed). For two control groups (Mexican ancestry natives and all natives), Table 7 reports the welfare participation results for female-headed households. Moreover, this table includes both the country model and the country/entry cohort model.

Mexican-born, female-headed households are more likely to participate in welfare than otherwise comparable Mexican ancestry natives, but the relationship is only marginally significant. When Mexican-born households are compared to all natives, no statistically significant differences are evident. The country/entry cohort model suggests that these results are due to offsetting tendencies for recent and more distant entry cohorts. Relative to each control group, more recent entry cohorts are less likely to use welfare but more distant cohorts are more likely to use it. These results provide further evidence that Mexican foreign-born households tend to use less AFDC but more SSI than their comparison groups. Again, these findings are reinforced by coefficients on the interaction terms that entail household members 65 or over (MEX65) and 17 or younger (MEX17). When more household members 65 and over are present, the Mexican-born households participate more than the native control group. The opposite is true when more household members 17 and under are present.

Specifically focusing on single, female-headed households narrows the population of welfare users to the broad group with the highest incidence of usage (Table 2). However, the empirical results for single, female-headed households presented in Table 8 are almost identical to those for all female-headed households, which suggests that the former group drives the results of the latter. The only substantive difference is in the country/entry cohort model with all natives as the control group. For all female-headed households, entry cohorts before 1960 participate significantly more than natives, but for single, female-headed

households this is not the case. The probable reason for this difference is that cohorts that entered before 1960 are somewhat older, and older single-female headed households are not likely to have young dependent children present as required for AFDC eligibility.

Tables 9 and 10 provide age-specific welfare participation results for all female-headed households where the respective control groups are Mexican ancestry natives and all natives. Relative to both control groups, recent entry cohorts (since 1975) of Mexican-born females less than 30 years of age are less likely to participate in welfare (AFDC). Relative to all natives, those who entered during the 1960s are more likely to participate. Moreover, those aged 30 to 49 who entered between 1950 and 1969 are more likely to participate than either control group.

Other factors held constant, including entry cohort, age at entry makes a difference in welfare participation. Relative to each control group, Mexican-born females between the ages 30 and 64 are less likely to use welfare if they entered at an older age. However, relative to all natives, those aged 65 and over who entered at older ages are more likely to participate (almost certainly in SSI), suggesting that SSI is being used in place of Social Security by the elderly foreign born who do not qualify for the latter.

Previously, we observed that Mexican-born households are more likely to receive welfare if they contain persons 65 or over, but are less likely to receive it if they have persons 17 or younger or who are disabled. Tables 9 and 10 provide more details. If their households include persons 17 or younger, Mexican-born, female-headed households under the age of 50 are less likely to use welfare than otherwise comparable households of Mexican ancestry natives and of all natives. If their households include persons 65 or older, they are less likely to participate than otherwise comparable households of Mexican ancestry natives and no more likely to participate than the households of all natives. The higher welfare usage of the Mexican-born, female-headed households arises from the group aged 50-64, and this finding holds for each control group.

The availability of AFDC plays an important role in the welfare usage of Mexican-born females below 50 years of age. Moreover, state supplements to SSI exert a significant influence on the welfare usage of those 65 and over.

The age-specific results for single, female-headed households show few significant differences between the Mexican-born population and the native-born control groups in terms of entry cohort (Tables 11 and 12). The only noteworthy coefficients suggest that single, female-headed households from Mexico under the age of 30 are less likely to participate in welfare than their Mexican-ancestry native counterparts if they entered the United States between 1975 and 1990.

Male-Headed Households

Male-headed households are the final group analyzed. Both the country and country/entry cohort models are estimated using both Mexican ancestry native households and all native households as the control group. The country/entry cohort model is then estimated by age group against both control group. The results generally indicate that the more recent Mexican-born, male-headed entry cohorts are less likely to participate than either native control group (Table 13). The more distant entry cohorts are more likely to participate than the control of male-headed Mexican ancestry natives, but are not statistically different from the control of all native male-headed households. Male-headed Mexican-born households with members 17 years old and younger are less likely to participate than either native control group, whereas those with members 65 years old and older tend to be more likely to participate.

The age-specific results presented in Table 14 (Mexican ancestry native control) and Table 15 (all native control) indicate that male-headed, Mexican-born households in the older three age groups are somewhat more likely to participate in welfare programs than otherwise comparable natives from each control group. For example, all eight entry groups in the 30 to 49 year old group are significantly more likely to participate than Mexican ancestry native households. Seven of the eight in this age group are more likely to participate than households in the all native control. Several of the entry cohorts in the 65 and over age group are significantly more likely to participate than male-headed households in each control group. Mexican-born, male-headed households with members 17 and younger are significantly less likely to participate than otherwise comparable natives. This result is consistent across both control groups and all age groups.

Summary and Conclusions

This paper presents an econometric analysis of participation in means-tested programs by Mexican-born households in the United States. Household-level records are created from the 1990 Public Use Microdata Sample of the U.S. Census. Several control groups are explored, as are several subsamples of the data, in order to provide a more complete analysis of welfare participation differences between Mexican-born and native-born households. Two models are run for most of the subsamples. The country model simply uses a dummy variable to distinguish between Mexican-born and native households. The country/entry cohort model is more detailed, replacing the country dummy with a series of eight entry cohort dummies. Furthermore, the data are separated into age groups for some of the subsamples in order to examine differences in participation behavior between the young and the old. This allows us to examine those

households more prone to AFDC usage separately from those households more prone to SSI usage.

The empirical results of this study indicate that Mexican-born households are no more likely to use welfare than either otherwise comparable native-born households of Mexican ancestry or otherwise comparable native-born households in general. However, they are more likely to participate than native whites, but less likely than native blacks. Moreover, recent cohorts from Mexico are less likely to use welfare than any control group, whereas more distant cohorts are more likely users.

Essentially the same basic results hold when households are partitioned into those headed by females and those headed by males. The highest incidence of welfare usage is among single female-headed households, but Mexican-born females in this group are significantly less likely to participate in welfare (AFDC) if they entered the United States in recent cohorts. This finding holds relative to different control groups, and it holds as well for young female household heads (less than 30 years old) born in Mexico.

The same general finding holds for male-headed households from Mexico, as well as for young male-headed households from Mexico. Recent entry cohorts participate less in welfare (AFDC) than otherwise comparable households both of Mexican ancestry and of all natives. However, Mexican-born male-headed households 65 years old and over who entered the U.S. in more distant cohorts show some tendency to use welfare (SSI) significantly more than otherwise comparable native-born households of Mexican ancestry. Although a similar relationship holds relative to all native households 65 and over, it is less strong.

Borjas and Trejo (1993) conclude that immigrants assimilate into welfare. Findings of the present study do not directly address the assimilation issue because we do not employ two Censuses to form synthetic cohorts that are followed through time. However, the present results suggest some caution in drawing conclusions regarding the assimilation of Mexican immigrants into welfare. When they are young, recent entrants in the U.S., the Mexican-born population is less likely to use welfare, which is almost certainly AFDC. When they grow older, or enter at older ages, they are more likely to use SSI.

In studies of this type, in which the foreign born are analyzed relative to a control group of native-born households, investigators may impute behavior to the foreign born when the native-born control is in some sense more responsible for a finding. The apparently higher use of SSI by the Mexican-born population is almost certainly due to their not qualifying for Social Security during their retirement years. The control group of natives has Social Security income available to it, which in turn lessens its reliance on SSI. Indeed, it is not clear whether the results of the present study are due to the lesser use of SSI by older natives or the higher use of SSI by older persons born in Mexico.

Notes

1. Although several other public programs could be analyzed, such as public schooling, and while one could also include Food Stamps and Unemployment Insurance in the welfare program group and Medicaid in the social insurance group, the analysis here is limited to the welfare programs AFDC and SSI and the social insurance program Social Security. This restriction is a direct result of the data set used, the 1990 Public Use Microdata Sample of the U.S. Census. See the section titled "Data" for more details.

2. Assimilation effects are only analyzed in Borjas and Trejo (1991).

3. Blau (1984) also analyzes the level of benefits received given participation. For male-headed Hispanic households, she finds that the level of welfare benefits received is significantly higher, and the level of social insurance benefits received is not significantly different, than that of male-headed non-Hispanic households. For female-headed Hispanic households, the level of welfare benefits received is significantly higher, and the level of social insurance benefits received is significantly lower, than for female-headed non-Hispanic households.

4. The adjusted rates are predicted from OLS welfare participation regressions in which age, education, marital status, year of immigration, and English language proficiency of the head, as well as the number of disabled household members, the age composition of the household, and household size are included as independent variables.

5. Tienda and Jensen (1986) and Jensen (1988) also examine welfare participation for Asian, black, and white immigrant and native households. These results are not discussed here.

6. To test the validity of our choice not to use the sample weights, some regressions have been run both with and without the sample weights. The results from the weighted and unweighted regressions are essentially the same.

7. The EDUC variable actually appears as HEDUC, for head's education, and SEDUC, for spouse's education, in the empirical work.

8. As with the educational attainment variable, in the empirical work below, EXPER appears as HEXPER, for head's experience, and SEXPER, for spouse's experience.

9. Since no explicit measure of private transfer income is available in the 1990 PUMS, we consider the 1990 Survey of Income and Program Participation (SIPP) in an effort to impute private transfer income into the 1990 PUMS. The SIPP is the only data set available that identifies private transfer income and provides detailed variables on foreign-born status. The core records from the 1990 SIPP are combined with the migration history variables from the 1990 Wave 2 Topical Module. Records are excluded and variables are created to as closely as possible match the format of the 1990 PUMS data set created earlier. The primary variable of interest in the 1990 SIPP is "money received from family or friends." This source of income can be identified by households as one of ten income sources from a list of 36 possible sources. If so identified, the dollar amount received in each month of the panel is also reported. These monthly amounts are converted to annual amounts to match the private transfer income definition that is needed in the 1990 PUMS. Descriptive statistics indicate that 404 of the 8663 households analyzed, or 4.7%, report receiving private transfers. Mean private transfer income among these 404 households is $2,177.77 with a standard deviation of $4,034.65 and a range from $3.75 to $30,375.00. By way of comparison, mean household earned income for this same group is $26,538.57.

Following Cox and Jakubson (1995), Cox and Rank (1992), and Cox (1987), a model is developed to explain private transfer receipt and the level of private transfers received.

The following independent variables are included in the model: age of the household head, age squared, education level of the household head, age interacted with education, sex of the household head, a dummy variable indicating the presence of a married spouse, household earned income, dummy variables for the race of the household head (Black, Asian, and Hispanic), a foreign-born dummy variable, and a dummy variable indicating the presence of foreign-born household members other than the head.

The model is estimated by each of two methods. First, a tobit model is fit to explain the amount of private transfers received by all households. The tobit model is appropriate here because it accounts for left censoring of private transfer income at zero dollars. Second, a two-stage model is estimated in which the first stage consists of a probit explaining receipt or non-receipt of private transfers. From this probit, the Mill's ratio is computed. The second stage then involves fitting a least squares equation to the level of private transfers received, with the sample restricted to only those households with positive private transfer income. The Mill's ratio is included as an independent variable in this regression to correct for sample selection bias.

Although both models produce generally significant coefficients of the expected signs, imputing private transfers into the 1990 PUMS based on these estimated coefficients produced negative values for all households. Given this result, private transfer income is not added to the 1990 PUMS data set, nor is it included in the empirical model reported below. However, the estimated coefficients on the foreign-born dummy variables are large, positive, and highly statistically significant. In fact, the foreign-born coefficient from the tobit model indicates that foreign born households receive nearly $1,800 more per year in private transfers than do otherwise similar native-born households. Notwithstanding these findings, private transfer income may be captured in the 1990 PUMS as part of the "all other income" measure included in non-labor income. However, even if this is the case, the effects of private transfer income on welfare participation cannot be separately examined.

10. Killingsworth (1983) discussed wage equations in the labor supply context. Friedberg (1993) analyzes wage and earnings equations including foreign-born characteristics.

11. Killingsworth (1983), Heckman (1979), and Maddala (1983), among others, provide very detailed discussions of this procedure.

12. The all native control represents a 10% random sample of all native-born households in the 1990 PUMS.

Appendix 1
Variable Definitions

Variable Name	Variable Definition
Household Characteristics	
PASTPART	Public assistance participation dummy (equal to 1 if household participates)
SSPART	Social security participation dummy (equal to 1 if household participates)
SOTHINC2	Sum of household's dividend, interest, and net rental income, retirement income, and all other income
SEXTFAM	Number of extended family members living in the household
SPOUSE	Equal to 1 if a married spouse or unmarried partner is present
ENGONLY	Equal to 1 if English is the only language spoken in the household
SHHLE17	Number of household members less than or equal to 17 years old
SHHGE65	Number of household members greater than or equal to 65 years old
SHHDISAB	Number of household members who are disabled
INMA	Equal to 1 if household is located in a metropolitan area
Head Characteristics	
LHWAGE	Head's log-wage
HSEX	Sex of household head (equal to zero if male, 1 if female)
HAGE	Age of household head
HEDUC	Head's years of completed education
HUNEMPLY	Equal to 1 if head is unemployed or not in the labor force
HWRKLIM	Equal to 1 if head has work limiting disability
HWIDOWED	Equal to 1 if head is a widow or widower
Spouse Characteristics	
LSWAGE	Spouse's log-wage
SAGE	Age of spouse
SEDUC	Spouse's years of completed education
SUNEMPLY	Equal to 1 if spouse is unemployed or not in the labor force
SWRKLIM	Equal to 1 if spouse has work limiting disability
SWRKPREV	Equal to 1 if spouse has work preventing disability

Appendix 1 (Continued)

Variable Name	Variable Definition
Foreign Born Characteristics	
MEXICO	Equal to 1 if household is of Mexican birth
MEX65	MEXICO interacted with SHHGE65
MEX17	MEXICO interacted with SHHLE17
MEXDISAB	MEXICO interacted with SHHDISAB
MEXWID	MEXICO interacted with HWIDOWED
MEXENG	MEXICO interacted with ENGONLY
MEXAFDC	MEXICO interacted with AFDCAVG
MEXSSI	MEXICO interacted with SSIAVG
ENTAGE	"Household's" age at entry into the U.S.
IMG8590	Equal to 1 if household immigrated between 1985 and 1990
IMG8084	Equal to 1 if household immigrated between 1980 and 1984
IMG7579	Equal to 1 if household immigrated between 1975 and 1979
IMG7074	Equal to 1 if household immigrated between 1970 and 1974
IMG6569	Equal to 1 if household immigrated between 1965 and 1969
IMG6064	Equal to 1 if household immigrated between 1960 and 1964
IMG5059	Equal to 1 if household immigrated between 1950 and 1959
IMGLE49	Equal to 1 if household immigrated before 1949
Area Characteristics	
AFDCAVG	State's average monthly AFDC payment
SSIAVG	State's average SSI payment

IMPACTS OF MIGRATION

Labor Market Implications of Scale, Innovation, and Entrepreneurship

*Michael J. Rosenfeld & Marta Tienda**

This paper addresses what is known about the impacts of immigrants on the U.S. economy, with special focus on Mexican immigrants. To stimulate critical thinking about whether Mexican migration warrants special policy consideration, it is necessary to first identify what is unique or distinctive about U.S.-bound Mexican migration. This a fair question because historically U.S. immigration policy has considered national origins in setting admission guidelines. Sometimes administrative policies for immigrants from different countries have been used to reinforce controversial international policies, as in the case of immigrants and asylum seekers from Central America during the 1980s, when refugees from El Salvador and Guatemala were systematically turned away, while refugees from Nicaragua were welcomed (see Teitelbaum and Weiner, 1995). The different treatment of unauthorized migrants from Haiti and Cuba during the 1990s offer another stark example of the intersection of foreign policy and immigration policy.

Our discussion of U.S. immigration begins by recognizing that migrant characteristics differ according to source regions and countries, and that these characteristics directly influence migrants' integration prospects and labor market

impacts in the host society. Most studies about migration make the simplifying assumption that the U.S. is a single, or perhaps divided (high wage and low wage) labor market. Frequently ignored are the reception factors, especially community-level circumstances, that facilitate the integration of new arrivals and organize links between immigrant enterprises and the mainstream economy. Most Mexican immigrants come not to an alien anglo environment, but rather to Mexican American communities within the United States where Spanish is spoken and where the customs and consumer tastes of the neighbors are well understood. This is relevant for understanding the labor market impacts of Mexican along with several additional factors that distinguish Mexican migrants from those who come to the U.S. from other source countries.

Size of the flow. Among the 18 million foreign born people living in the U.S. in 1990, more than 4 million, or 24% came from Mexico (see Table 1). Mexico contributes a larger share to the foreign born population of the U.S. than any other country, and roughly as much as the entire continents of Asia and Europe.

Duration of the flow. In the decade 1911-1920, 219,000 Mexicans legally immigrated to the U.S (Bean and Tienda, 1987). In the 1920s, this flow more than doubled. The 1930s and 1940s were slow times for all kinds of international migration except for war refugees. Migration from Mexico picked up again in the 1950s (299,000), and the flow has steadily increased to more than a million legal Mexican immigrants in the 1980s. The Mexican share of legal migration is lower than the Mexican proportion of foreign-born in the U.S. because the foreign born population also includes undocumented (i.e., illegal) immigrants.

Residential Concentration and "Sister" Communities. For historical reasons, the Mexican origin population is residentially concentrated in the five Southwestern states and Illinois. Within these locations, Mexican immigrants tend to reside in the largest metropolitan areas. Moreover, there are sizable established Mexican American communities in cities such as Los Angeles, Chicago, San Antonio and Houston. In 1990 there are just under 9 million U.S. natives of Mexican descent (see Table 1).

Motives for Migration. The Mexican immigrant flow includes negligible numbers of refugees or political asylum seekers. Virtually all Mexican immigrants seek better economic opportunities in the United States. However, social and familial ties to established Mexican American communities in the U.S. also draw immigrants across the U.S.-Mexico border.

Undocumented Immigration: Mexicans represent the bulk of undocumented migrant flows. Data on undocumented migrants is necessarily sketchy. However, studies of legalization authorized by the Immigration Reform and Control Act (IRCA) of 1986 indicate that 70% of those who were legalized under the amnesty program were of Mexican origin (see Tienda, et al., 1991; Singer, 1994).

Educational Attainment. The Mexican immigrant population comes to the U.S. with low levels of formal education. Male Mexican immigrants average nine years of education (see Table 2), which is substantially less than most other native and immigrant groups, who average a high school education. Because Mexico has been the single largest source of migrants to the U.S. for 30 years, and because migrants from Mexico have low levels of formal education, there has been much concern in recent years about declining skills of recent immigrants, and Mexican streams in particular.

Low Wage Workers. As a corollary to the low educational attainment of Mexican immigrants, Table 2 shows that male Mexican immigrant workers (excluding farm workers) averaged an hourly wage rate of only $8 in 1993, which is considerably lower than most other native and immigrant groups. The annual average wage and salary income of male Mexican immigrant workers hovered around $15,000 in 1993, almost 50% below that earned by non Hispanic white immigrants and 24% below that earned by U.S.-born Mexicans.

Labor Force Participation. Adult male immigrants from Mexico participate in the labor force at a rate of about 80% (see Table 2), which is higher than the average rate of both native and immigrant men of comparable ages. One reason for Mexican immigrants' higher labor force participation than other immigrants is age structure. Mexican immigrants are relatively young: only 1.4% of all Mexican immigrant male adults are retired, as compared with 7.8% for all immigrant male adults, and 12.9% for all native born adult males. Mexican immigrants may also work more in their older years or perhaps may not live long enough to enjoy a lengthy retirement (or may retire back to Mexico); the sample size of the Current Population Survey (on which Table 2 is based) is not large enough to allow for deeper study of this question.

All of these features of U.S.-bound Mexican migration—its volume; history; socioeconomic and demographic composition—would appear both to justify and warrant bilateral policy considerations. This is all the more so because the 2,000 mile shared border facilitates unregulated entry and poses special challenges for both the Mexican and U.S. governments. Because Mexican immigration does not include many refugees (whose entry into the U.S. satisfies humanitarian or global political criteria), it is reasonable, as a first step, to address the policy issues of Mexican immigration as a simple cost and benefit problem for the U.S. economy: if Mexican migrants are beneficial for the U.S. economy, then less restrictive immigration policies would be appropriate. If Mexican immigration is harmful to the U.S. economy, then restrictive policies are justified.

Before turning to a discussion of the different ways that international migration, and Mexican immigration in particular, may effect the U.S. economy, we offer two comments. Our reading of the recent literature about the economic impacts of

Table 2
Wages and Work Force Participation for Males

A) U.S.-born Male Workers

Ethnic group	LFPR	Number of workers in (000)	Workers' mean years education	Mean 1993 wages	Mean number of weeks worked 1993	Hours worked per week	Mean constructed hourly wage
Mexican	73.51%	1,195	12.10	$19,429	44.40	38.90	$10.51
Other Hispanic	67.93%	775	12.50	$20,497	46.00	40.10	$10.59
Non Hispanic Black	63.54%	4,176	12.50	$19,976	44.20	38.50	$10.83
Non Hispanic White	76.92%	48,445	13.50	$27,287	46.00	41.60	$14.68
Non Hispanic Other	73.83%	1,178	13.00	$17,668	37.50	38.70	$15.71
TOTAL	75.65%	55,769	13.37	$26,274	45.65	41.23	$14.27

Table 2 (Continued)

B) Foreign-born Male Workers

Ethnic group	LFPR	Number of workers in (000)	Workers' mean years education	Mean 1993 wages	Mean number of weeks worked 1993	Hours worked per week	Mean constructed hourly wage
Mexican	79.87%	1,427	9.40	$14,855	46.00	38.90	$8.10
Other Hispanic	74.51%	870	12.10	$20,045	44.70	40.80	$10.73
Non Hispanic Black	67.24%	315	14.00	$19,664	44.10	41.90	$10.29
Non Hispanic White	71.72%	1,825	14.00	$28,823	44.70	40.60	$15.51
Non Hispanic Other	80.79%	1,582	14.70	$27,847	46.50	39.70	$15.94
TOTAL	76.20%	6,019	12.82	$23,507	45.45	40.06	$12.90

immigration, and our own research (including a survey of households and businesses in the mostly Mexican Chicago neighborhood called Little Village) leads us to believe that immigrants in general, and Mexican immigrants in particular are probably beneficial to the U.S. economy. We will endeavor to justify this assertion in the remainder of this paper.

The second comment relates to the efficacy of restrictive policies toward Mexican immigration. Rather than discuss specific policies in this paper, we simply note that the duration of U.S.-bound Mexican migration and the resultant size and vibrancy of the established Mexican American communities in the U.S. makes control very difficult because migrants can tap into social and familial contacts in the established Mexican American communities (which lowers the cost of migration). Massey, Donato and Liang (1990) have expressed informed skepticism about the deterrent effects of IRCA. Massey's work on immigration has emphasized the strength of social and familial ties as factors that draw Mexican immigrants to the U.S., and the impotence of governmental policies that attempt to restrict immigration after sister communities are established in the United States. Zolberg (1995) has called attention to the perverse effects and unintended consequences of U.S. immigration policies. We raise this point simply as a cautionary note for policy discussions; the complexity of the real world is humbling for those of us who work on policy issues, particularly when framed in narrowly economic terms.

The Economic Impacts of Immigration

Academic studies about the economic impacts of immigration are concerned with various different types of impacts. Accordingly, we adopt Greenwood's (1994) language in which he refers to separate and distinct channels of influence through which immigration impacts the economy of the host society. In this paper we discuss a few these channels of influence, paying special attention to labor market impacts. We will treat only briefly the most commonly studied channel of influence, that is, the direct effect of immigrants on the wages of natives. One common view of immigration sometimes found in the mass media is that immigrants take jobs away from native workers, or exert a downward force on wages by accepting lower wages than comparably skilled native workers. Immigrants, however, also create jobs by their own demand for goods and services, and immigrant workers can be complements as well as substitutes for native workers. The net effects of immigrants on the wages of natives is therefore difficult to measure, although many have tried.

The second most frequently studied channel of influence focuses on the direct fiscal impact of immigrants, and we will again be brief with this topic. Fiscal impacts concern the current account balance between what immigrants pay in taxes and

fees with what they consume in tax-supported amenities and services. Mexican immigrants earn low wages, and therefore pay lower than average income tax. Mexicans also have larger than average family size, so they may consume more in public education services than they pay in local taxes. The issue is complicated, as we note below, by the fact that Mexican (and other) immigrants pay their share of Social Security taxes, a regressive tax, and many immigrants are ineligible for Social Security benefits. We will take up the issue of fiscal channel of influence with a brief literature review below.

Instead of focusing on the labor market channel of influence, or the fiscal channel of influence, both of which have been extensively analyzed, albeit inconclusively, we focus instead on the channels of influence that derive from economies of scale, and the special contributions that immigrants may make through their inventiveness, motivation, and self-selection for willingness to work hard in order to improve their lot in life. The former consideration is important for Mexican immigration because of the sheer volume of the flow, while the later is relevant because the low educational attainment of Mexicans relative to other immigrants and U.S. natives leads to the partly inaccurate inference that Mexican immigrants are unlikely to be entrepreneurial. To make our case on these two points, we draw on a recent survey of entrepreneurship in the Mexican neighborhood of Little Village, Chicago.

The Labor Market "Channel of Influence": A Brief Comment

Borjas and Tienda (1987) summarize many of the empirical studies of wage and labor market impacts of immigration, with the general finding that immigrants' impact on the wages of natives are barely significant, while impacts on the wages of earlier cohorts of immigrants are discernible, albeit small. Greenwood and McDowell (1993) also provide an extensive survey of this literature, therefore we provide only a few comments. The first point is that, as Borjas (1994) notes, there are some methodological and empirical shortcomings of this line of work. Most of the labor market studies use the number of immigrants in a city as a measure of the immigrants' influence in a particular labor market. One problem is that natives may migrate internally in response to immigration (for instance, to avoid immigrants) so that the correlation of immigrant presence with low native wages may simply represent the effect of selective internal migration by natives.

A second problem has been highlighted by Card's (1990) empirical study of the massive and sudden wave of Cuban migration to Miami in 1980, known as the Mariel boat lift. Card has shown that this sudden wave of mostly low skilled migrants, which in the course of 6 months increased Miami's work force by 7% (60,000 people), had no perceptible impact on Miami's labor market for either

natives or for previous Cuban migrants. This surprising result implies that the economic impacts of migrants are not so easily isolated to their city of entry or residence as has been previously assumed. Considering that the Mariel boat lift corresponded to a wave of migration that was a full order of magnitude larger (relative to the work force of Miami) than most of the empirical studies are able to contemplate, and that no impacts were found, Card's study raises fundamental questions about the efficacy of the econometric literature on labor market impacts of migration.

The Fiscal Channel of Influence

Empirical studies about fiscal channels of influence has been weighted down by studies that examine only part of the fiscal picture (i.e., welfare) and studies that examine only local impacts. Simon (1984, 1989, and 1996) has presented a series of analyses based on the most comprehensive data source available, the 1976 Study of Income and Expenditures. He showed that immigrants are net fiscal contributors to the U.S. economy mainly because they contribute to, but do not receive benefits from the Social Security program. This is because immigrants have a high worker to dependent ratio, and because immigrants of retirement age are generally not eligible for benefits. Social Security is a federal program, and Simon points out, as do Greenwood and McDowell (1993), that much of the fiscal burden of immigration is felt by states and localities.

The peculiarities of the distribution of the fiscal effects of immigration implies that local and state governments probably are burdened by immigration, but that this burden is more than balanced by immigrants' support of Social Security. The fiscal burden felt by states and localities in regard to immigration is, therefore, not a real "cost" of immigration, but rather a problem in the fiscal balance between the federal government and the states, and more specifically between the states with few immigrants (whose retirees are partly subsidized by immigrants) and the immigrant receiving states. Precisely because they ignore federal programs like Social Security, studies that focus on local fiscal impacts, such as Mines and Martin (1986), Muller and Espenshade (1985) and McCarthy and Valdez (1986), have left the possibly mistaken impression that immigrants are a fiscal drain on the U.S. economy.

Rothman and Espenshade (1992) were rather critical of Simon's analysis for two reasons. One reason is that Simon aggregated immigrants of all national origins, and the second is that he applied national average figures for taxation and per pupil school expenditure to populations that are not evenly distributed across the country. Neither criticism invalidates Simon's inference that Social Security payments by immigrants make them net fiscal assets to the U.S. economy (although the lack of

national disaggregation does pose some problems for applying Simon's findings to the case of Mexican immigrants only).

In the particular case of Mexican immigrants, the issue of fiscal impacts is complicated by the fact that there are legal and illegal immigrants, who use services and transfers at very different rates, and whose contributions to Social Security and to federal taxes differ depending on whether they are formally or informally employed, and depending on their legal status in the United States.

Heer (1990) and Weintraub and Cardenas (1984) claimed that undocumented Mexicans use fewer services or transfers (because they are either not eligible for them, or are wary of any contact with officials). This implies that undocumented workers are essentially a fiscal windfall for employers and also for state and national coffers (because they do pay taxes). Weintraub and Cardenas (1984) estimated that the state of Texas received a fiscal benefit of at least $120 million per year from undocumented aliens (mostly Mexicans), although Rothman and Espenshade (1992) point out that Weintraub and Cardenas' data is based on a nonrandom interview sample. Undocumented workers occupy a peculiar space in the rhetoric about immigration. Undocumented workers, or illegal immigrants. are the object of much political backlash against migration, yet (if Heer and Weintraub and Cardenas are correct) they may be the most fiscally beneficial of migrants.

Economies of Scale and Innovation

The first modern essay on population growth and the economy is credited to Malthus, who assumed that natural resources were fixed and that therefore a larger population would necessarily mean a lower standard of living for everyone. Simon (1993) notes that Malthus wrote five different editions of his famous essay, and each subsequent edition was less alarmist about the consequences of larger populations. Adam Smith and the other early innovators of modern economic theory took a different view. For Smith, a greater population meant a greater division of labor, which implied greater efficiency and product per person, and therefore increasing returns to scale; twice as many workers would create more than twice as much product. One of Smith's famous examples is the pin factory, where the manufacture of pins is divided into eighteen different tasks, each performed by one person. The assumption is that such specialization (for which a substantial population is a necessary ingredient) leads to greater efficiency, and greater per capita production.

Simon (1993) cites a number of 19th century economists who directly confronted Malthus' initial supposition that natural resources are fixed; he quotes Henry George who wrote "Both the jayhawk and the man eat chickens, but the more jayhawks the fewer chickens, while the more men the more chickens." This same anti- Malthusian

view is developed at some length in Simon (1989). The basic premise is the classical economic notion that the price mechanism ensures that as demand for a given natural resource rises while supply falls, technology and innovation will be applied to find more or to create substitutes for the important resource. Simply put, the greater the human demand for chickens, the more farmers will devote themselves to new and more efficient ways to produce chickens. Technology, in other words, overcomes some of, if not all, the apparent limits of natural resources. Not all resources are as easy to replenish as chickens, of course, and Simon takes his argument considerably further. He argues that, despite the claims of the environmentalists, natural resources from fresh water to forests to oil reserves have never been more plentiful (at least in terms of the resources that are directly accessible by society).

Since the past two centuries of history in the developed world has proven that Malthus' alarmist view of population growth is insufficient, Preston (1989) and Simon (1989) and others have reemphasized the positive economic potential of population growth. Some public goods, such as national defense, do not depend directly on the size of the population. An increase in population ought not to increase the need for national defense, but would increase the number of people paying for defense, thus lowering the cost per capita and lessening the burden on the native residents; this would be experienced as a direct increasing return to scale. Most services are not like national defense in that an increase in population would ordinarily require an increase in services provided (education, police protection, health care, electricity and sewer service to name a few). If the marginal cost of providing a service decreases as the populations grows (holding the quality of the service constant, which is easier to do in theory than in practice), then population growth will lower the per capita cost of that service and everyone will benefit from increasing returns to scale.

In theory (and usually in practice), an increasing population leads to higher population density, and higher density areas receive most services at a lower cost per person. For example, rural electrification costs much more per person served than urban electrification. Some rural schools may be less costly per pupil than urban schools, but unlike the provision of electricity the quality of education services is not easily comparable. Preston (1989) points out that in the United States, which has a relatively low average population density, the majority of the population is crowded around large metropolitan areas, leaving many rural counties almost vacant. Workers in the city earn more than rural workers, and city residents have access to many goods and services that are unavailable in rural areas. The residential settlement patterns of U.S. residents seems to be evidence that economies of scale are a real force drawing people to settle in areas of higher concentration. Both Preston and Simon cite the powerful Japanese economy, with high population density and few natural resources, as an example of the continuing relevance of economies of scale.

The Japanese enjoy minimal transportation and communication costs because their population density is so high.

On the question of returns to scale and economic history, the central figure is Simon Kuznets. Kuznets (1960, [1967] 1973, [1972] 1973) argued that not only are there increasing returns to scale in industry because of greater specialization and because of technological innovation, but that technological innovation itself is subject to a scale economy. The reasoning is as follows: there are a fixed proportion of innovators and geniuses in any population. Because different branches of knowledge are interrelated, and because engineering and technical innovations rest on an established base of knowledge (the cumulative effects of earlier innovations), it stands to reason that larger societies will have a greater number of innovators and geniuses (because of sheer numbers). Furthermore, this larger number of innovators and geniuses will feed off each other's work to create an economy of scale for innovation, which will in turn make the entire society more efficient. As Kuznets writes (1960: 328), "The greatest factor in growth of output per capita is, of course, the increasing stock of tested, useful knowledge."

If there are in fact increasing returns to scale as Kuznets and Simon and the classical economists claimed, the implication for immigration is fairly clear: more people make the whole society more efficient, and immigration, on balance, should be beneficial to the host society. The issue is, of course, more complex because there can also be diseconomies of scale, and because the extent of increasing or decreasing returns to scale is the subject of substantial disagreement in the empirical literature. The question of returns to scale is central, however. The pro-immigration studies generally assume, as Simon (1989) does, a positive return to scale for population growth. And most anti-immigrant work emphasizes over crowding, over use of limited resources, and other implicit decreasing returns to scale for population growth.

The economic literature that employs explicit models for the impacts of immigration, such as Borjas (1995), almost invariably assumes constant returns to scale in the production functions. Despite the fact that the measurement of real returns to scale presents many empirical problems, and therefore the assumption of constant returns to scale is a defensible assumption, we believe that this common assumption builds an inherent bias against possible economic benefits immigration. Kuznets' economic history of the U.S. makes a strong case for the importance of returns to scale over time, and Simon has pointed out that there is little reason to believe these historical arguments are any less relevant today.

The returns to scale issue is further complicated for the case of Mexican immigrants because Mexicans are, on average, the immigrant group with the fewest years of formal education (see Table 2 and also Chiswick, 1986; Borjas 1992; Borjas and Freeman 1992). This means that arguments about the innovative capacity of

Mexican migrants may be a bit harder to make. On the other hand, the size and duration of the flow of migrants from Mexico (and the resultant size, development, and division of labor within the established Mexican American communities) provides many possibilities for scale economies internal to the Mexican American neighborhoods themselves.

As we will see in the vignettes from our Little Village (Chicago) survey, this immigrant Chicago neighborhood has enough Mexicans to support a fully differentiated economy of goods and services. Because the Little Village community is growing, and because the consumer tastes and language of the Little Village residents is best understood by other co-ethnic residents, there are ample opportunities for business, entrepreneurship, and economic innovation in Little Village and in other Mexican American communities. Little Village, in other words, is conducive to a myriad of formal and informal economic activities which are largely invisible to formal accounting systems and surveys. Moreover, there is more economic innovation in these communities than the low level of formal education of the Mexican migrants might lead one to believe.

Arguments about national level diseconomies of scale generally rest on the inefficiency of large enterprises due to inertia and the inability to change and adapt. Robinson (1960) presents multinational data on the cost of national administration (health, education, services and defense), and argues that the large countries (which in most of his samples, means the U.S.) are not necessarily more efficient in providing services than the smaller countries (Great Britain, France, Italy, Jamaica). Robinson's data shows that U.S. spends less per capita on national administration, except for defense where the U.S. spends far more. The problem with this kind of data is that there is no way to account for differences in the quality of the services provided, so one does not know whether India is either a tremendously efficient provider of national services, or a provider of very sparse administrative services (the latter is probably closer to the truth). Robinson (1960: xvii) makes the rather bold claim that 'it seemed to be our general impression that most of the major industrial economies of scale could be achieved by a relatively high- income nation of 50 million,' which would imply, of course, that the U.S. is far too big to enjoy any further advantages from scale economies. The problem, however, is that the 50 million person limit is arbitrary, and no empirical data or sound reasoning is cited to support it.

Jewkes (1960) makes an argument about the diseconomies of scale that seems to contradict Kuznets directly on the issue of economies of scale for innovation. Jewkes argues that although there are some examples of large corporate research and development making technological breakthroughs that would have been impossible for individual inventors to make (he cites the DuPont corporation's invention of Nylon), most inventions are made by individuals working alone. Jewkes

points out that the aircraft jet engine was invented simultaneously by a British air force cadet and a German undergraduate, working by themselves. In terms of Kuznets' theory, what is relevant for our argument is that the inventors of the jet engine lived in the well populated developed countries, and were therefore able to take advantage of a stock of knowledge, and had access to other innovators and ideas that would not have been available to an equally talented inventor living in Costa Rica or Belize. The invention of the jet engine by two separate individuals does not, therefore, undermine the idea of scale economies in knowledge.

When Kuznets refers to innovation and technology as the engines for economic growth (see Kuznets [1972] 1973), he mainly refers to technologies like the steam engine, the light bulb, the telephone, the internal combustion gasoline engine, or the more recent advent of atomic energy. These technological advances have had profound and lasting effects on the economy, without doubt (although the legacy of atomic energy may not be as clear as Kuznets imagined). But Kuznets' emphasis on the highest levels of technological input leave open the question of whether working class immigrants can be considered as advantages in a scale economy of knowledge, which according to Kuznets' examples, would seem to favor mainly the immigration of physicists, engineers, doctors and other highly trained people.

Simon (1989: 175) offers one answer to this question. In his words:

> It cannot be emphasized too strongly that 'technological advance' does not mean only 'science' and scientific geniuses are just one part of the knowledge process. Many technological advances come from people who are neither well educated nor well paid: the dispatcher who develops a slightly better way of deploying the taxis in his ten-taxi fleet; the shipper who discovers that garbage cans make excellent cheap containers; the supermarket manager who finds a way to display more merchandise in a given space; the supermarket clerk who finds a quicker way to stamp prices on cans; the market researcher in the supermarket chain who experiments and finds more efficient and cheaper means of advertising the store's prices and sale items and so on.

Simon appropriately acknowledges that it is not only the Enrico Fermis and Albert Einsteins who contribute to knowledge and hence economic efficiency, but also motivated, entrepreneurial and innovative immigrants who, despite a lack of formal education, may contribute to a society's economic well being. It is well to remember that much of the economic literature assumes that years of schooling is a direct measurement of skill and hence of worker productivity. Simon (1989) argues that immigrants bring with them knowledge based on the experience of how things are done in other places, and may therefore be highly productive in their host society despite a limited formal education. The burgeoning literature on ethnic enterprise in America would appear to support this view.

Supplementary to Simon's argument about working class innovation and entrepreneurship are studies that consider how immigrants may be self-selected for entrepreneurial spirit and work ethic. Chiswick (1978: 901) argues that the good performance (in excess of what their moderate schooling levels would lead one to expect) of immigrants in the U.S. economy is evidence that the immigration process self selects migrants for 'motivation' and 'innate ability.' Chiswick's empirical findings have been repeatedly questioned by Borjas (1992, 1994) who argues that Chiswick confused an assimilation effect with a cohort effect; Borjas' point is that there has been a decline in immigrant skills rather than an assimilation of immigrants over time.

Borjas (1992) refers to the declining skills of recent immigrant cohorts, but his own tables show that overall immigrant educational attainment has risen steadily over time (from 9.5 years in 1940 to 12 years in 1980); U.S. native educational attainment has simply risen faster, so that it is not immigrant skills that are declining but rather U.S. native skills (measured by years of education) that are outpacing the skills of the immigrants, and precisely at a time when the returns to skill have been rising markedly. The educational attainment of Mexican male immigrants to the U.S. has crept up from about 7 years in the 1950s to a bit less than 9 years today (in our Table 2, their educational attainment is reported as 9.4 years, but this is for only non agricultural workers; the full sample of Mexican male immigrants has 8.7 years of education). As such, the "skills" of Mexican immigrants (as measured by education) have not declined over time. The education gap between Mexican immigrants and natives may have increased over time, but Chiswick's analysis still rests on the advantage that immigrants have due to their self-selection for determination and creativity, if not formal schooling. Since both Chiswick and Borjas rely mainly on cross sectional data from the decennial census, it is not entirely possible to adjudicate between their competing conclusions interpretations because neither can adequately model period effects which have greatly altered opportunities for earning a living.

Kao and Tienda (1995) have recently demonstrated a result which bolsters Chiswick's idea that immigrants are self selected for innate skill and motivation. Using the National Education Longitudinal Survey (NELS:88), they showed that the children of first generation immigrants have higher scholastic aspirations and test scores than their native-born counterparts of similar socioeconomic standing. Although the effect that Kao and Tienda measure is strongest for the children of Asian immigrants, the children of Hispanic immigrants also seemed to benefit from this optimism and strong immigrant work ethic.

If Mexican immigrants are self selected for innate skill and motivation, it is partly due to the fact that Mexican immigrants come to the U.S. for economic opportunity rather than fleeing Mexico for political reasons. Political refugees, as

Chiswick (1978) notes, migrate for noneconomic reasons, and therefore would not necessarily represent the most fit, able, or motivated citizens. Economic migrants (like the Mexican migrants), who assume the costs and risks of migration would naturally be most likely to migrate if they considered their own abilities and determination would produce higher returns in the destination country. This, at any rate, is the rationale for believing that economic immigrants might be self selected for innate ability. There is, of course, no direct way to measure innate skills. What we offer, instead, is a glimpse into the Little Village neighborhood of Chicago which shows substantial levels of economic activity and entrepreneurship.

Mexican Immigrants' Entrepreneurship and Innovation

The Little Village Household Survey, hereafter LVHS, consists of in depth interviews from 330 households in Chicago's mostly Mexican Little Village community (see Tienda and Raijman, 1996 for a more detailed description). The survey uncovered considerably higher rates of self employment and informal employment for Mexicans (especially Mexican immigrants) than had been previously found. According to 1980 U.S. Census figures (Fratoe, 1986), 4.9% of all Americans were self employed. Some ethnic groups, such as Russians and Lebanese, were self-employed at rates approaching 10%, while for Mexicans the self-employment rate hovered around 2%. According to the LVHS, self employment rates for Mexicans in Little Village were about 10%. While the higher rate of self employment may be partly due to the urban setting of the Little Village community (which excludes the farm worker population, almost none of whom would be self-employed), the LVHS in-depth interviews also uncovered that much self employment occurs in the informal economy, which is a kind of economic activity that standard surveys seldom detect.

Following Portes and Sassen-Koob (1987), we note that the level of self employment, and especially self employment via informal activities, can be viewed as a source of economic innovation at the margins of a developed economy (there is considerable debate about the value of the informal sector in both developing and developed countries; see Portes and Schauffler 1993 for a review). In fact, according to preliminary analysis of the LVHS, many Mexican migrants have charted a labor market history that starts with low wage employment, proceeds to a mixture of low wage jobs with informal self employment to smooth income levels, and sometimes proceeds to full-time informal self employment. A sizable proportion of the formally self employed Mexican immigrants in Little Village started those businesses in the informal sector, so that the informal economy can also be seen as a pipeline into the formal economy. By definition, informal

businesses do not pay taxes and license fees, which is seldom examined by analyses who estimate the fiscal balance between immigrants and natives. Before going further into the possible benefits and drawbacks that immigrant entrepreneurship entails for the wider economy, we turn to a LVHS interviews themselves for examples. Consider the case of Yolanda (now age 40) who immigrated from the Mexican state of Jalisco to Chicago in 1975. She has a second grade education, and is married with 8 children. The following is a verbatim excerpt from her interview.

> She came to the U.S. with economic necessity and she had always like the fruit business. She went to Maxwell Street where there was a man who sold fruit. She started selling fruit (tomatoes) for the man without him telling her to do so. He like the way she sold fruit and within 3 weeks, he looked for her to ask her to help him sell in the flea market. He paid her $25 per day. One day, he made her cry in front of everyone. He accused her of stealing $25. She held in her anger and stayed there, but she started thinking that maybe she, too, could sell fruit and that way nobody would humiliate her. She told the man she was going to steal whatever she could. Within 3 weeks she stole $100. She returned the money to him to show him that she was no thief. But because he had humiliated her, he gave her the money. Then she began to study the way he sold, where he got his merchandise, how much he sold it for, etc. Then she asked him to pay her with vegetables instead of with money so that she could sell them. She got a grocery cart (she said she found it in the street—she stressed that she didn't steal the cart). She sold the merchandise that he gave her and made almost twice the amount she earned by working with the man. She saved a little and bought whatever she could from the man so that she could sell it. With $250 she set up a stand at Maxwell Street (a flea market in Chicago). In three years she saved $1000, plus $10,000 for a down payment on a house. When she found out that Maxwell Street would be closing, she decided to open up a store. With $1000 she started the store 2 years ago and until now, she has invested $30,000 in it. She has no debts; she didn't ask for loans because she doesn't like debt. She started the business on her own and she continues to develop it on her own.

The first point to be made about Yolanda's story is that, as Simon (1989) has pointed out, economic innovation can originate among persons of all social classes. Yolanda's second grade education and modest income did not keep her from finding a better way to sell tomatoes. The second point concerns how much immigrants "take" from the host society in their endeavors to find a better life for themselves. For this question, we take Yolanda's shopping cart as a metaphor. If, as Yolanda claims, her shopping cart (with which she started her fruit selling business) was indeed simply "found in the street," we see the immigrant taking resources that are

essentially wasted and returning them into the economy by dint of their own hard work and innovative use.

If, for a moment, we imagine that Yolanda (perhaps a different Yolanda) had stolen the cart, we get the other side of the economic argument. If the cart had been stolen, then Yolanda was not contributing to efficiency but simply cutting in on an already existing market for retail fruit, and perhaps undercutting the sales of a legitimate retail fruit store by selling fruit from a stolen cart without paying any sales tax to the state.

The question of fiscal contributions is a bit more complex, but it seems that Yolanda eventually is also contributing through this economic channel of influence. At first, Yolanda works for the other fruit merchant, and we can assume that no income taxes are being paid from Yolanda's $25 a day salary, and no sales taxes are paid from sales in the Maxwell Street flea market. In the second stage, Yolanda is selling fruit from her own cart, and again we can assume that no sales taxes are being paid. In the third and final stage, Yolanda is reinvesting her money into a house and her own fruit store, which denotes a shift from the informal to the formal economy. In the final stage, Yolanda is presumably paying taxes on a business and a property that were capitalized out of her own effort and creativity. Sassen-Koob (1989) describes the tension between immigrant informal economies that innovate, create and incubate entrepreneurial ideas (and are presumably an asset to the overall economy) versus informal sectors that simply represent tax and regulation avoidance by subcontractors tied to larger, formal firms (this kind of informal business is presumably a drain on the overall economy). Both kinds of informal businesses exist in Little Village.

As Yolanda's story is a bit unusual, we offer a few other representative stories taken from the Little Village survey. Hugo, age 48 was born in Mexico and has a U.S. born wife, two children, and a Mexican high school education. His father worked on the railroads in Mexico. Hugo started his own business because he did not want to work for others.

> I started this business in 1985 after working for the Lawndale Bank as a vice president. There I discovered that many people wanted to send documents and letters to Mexico and since no one offered this kind of service I decided to establish this business. It took me a year to acquire sufficient understanding of this area. I decided to start this business because of the demand by the people for the service; in this area there are many people that come to make deposits and I think that if they had more education it would work better but none the less we are growing.

Jesus was born in Mexico, immigrated to Chicago in 1965, and now lives with his wife, one child and his mother in law. Jesus had a third grade education in

Mexico. He had been part owner of a restaurant in Nuevo Laredo, Mexico and sold it to come to the U.S.; he says he thinks about business all the time.

> In 1968, there was no latinos here, I was one of the first. The neighborhood was Polish. I rented a garage in which I sold tortas and food. I began to let them taste my food- tacos and everything and I began to do better and better. It was a small place- a garage. I formed it into a restaurant. I paid rent to a Polish man, when he saw me working hard, he promised to sell it to me. In 1972, the owner of the building financed and sold it to me. It's been 25 years.

José and Efigenia are from Tamaulipas, Mexico and are both over 50 years old. José reports zero formal education. He says he went into business to be independent.

> I came illegally to the U.S. from Mexico where I was a barber. I started working as a barber in my house, and when I had sufficient clientele I rented a small place which was completely equipped, and that's how I got to the first level. After a long time, I got my savings together and started my own business with my own equipment, although I still rent the space.

The modest stories of Hugo, Jesus, José and Efigenia illustrate a few important points about Mexican migration to the U.S. Despite a lack of formal education, both Jesus and José exhibit the traits of entrepreneurship. Both abandoned businesses in Mexico in order to come to the U.S. where, presumably, they expected to receive better returns for their skills. Admittedly, this is circumstantial evidence for the theoretical proposition that immigrants from Mexico, and other non- refugee countries are self selected for innate skill, or entrepreneurial spirit. But absent direct empirical evidence, many have concluded that low education levels are inconsistent with innovation and entrepreneurial activity.

A second point relates to the size of Chicago's Mexican American community, and the differentiated economy that is implied by residential concentration within the city limits. Because Little Village was (or became) populous and diversified, there were ample opportunities for new and innovative kinds of businesses, like Hugo's document and currency transmission service. The information that Hugo needed in order to start his business was an experiential knowledge based on having lived in Mexico and the U.S., and having contact with the consumer needs of households in Little Village, rather than formal education.

Conclusion

The literature on the effects of population growth on economic development is justifiably modest in its claims and predictions. Kuznets himself ([1967] 1973)

readily admitted that increased population could have different impacts on an economy, depending on many factors, and that therefore there is no single "population effect." Mexican migrants to the U.S. are almost always viewed in the recent literature as low wage labor market drones- people who are willing to work picking lettuce or sewing pants in a factory for just a few dollars a day. The bulk of the literature then turns on whether this low wage labor is more beneficial to the U.S., or detrimental because the migrants exert a downward pressure on wages and also use state services. Our point in this paper is that Mexican migrants, despite their low average formal education, may contribute significantly to the U.S. economy through economic and cultural innovations, and returns to scale for a larger population.

Direct national returns to scale may be due to a greater national division of labor, or to a larger number of persons to share fixed costs, such as defense (since the cost of defense does not depend directly on the number of residents, a larger population would presumably lower per capita defense costs). The country as a whole may also benefit from a larger population due to an increased number of technical and practical innovations; this is Kuznets' theory and Simon has reminded us that beneficial innovations can come from people of any class or educational background. While the flow of immigrants from Mexico may provide a somewhat lower yield of scientific innovations (because of the low proportion of Mexican immigrants who have postgraduate education), the Mexican migrants are able to take advantage of a different, local kind of scale economy. Because of the size and duration of the flow of migration from Mexico, Mexican migrants are integrated into the U.S. economy through Mexican American communities that are themselves large enough and diverse enough (especially the urban neighborhoods like Little Village in Chicago) to support innovative new businesses.

Mexican immigrants are workers; their labor force participation is high because they come to the U.S. in their prime working years. Because the flow of Mexican migrants is so heavily weighted toward young workers and contains so few retirees, Mexican immigrants make an especially positive fiscal contribution to the national Social Security program. Mexican migrants may also be self selected for talent, motivation and innate skill, as Chiswick would argue, which would imply that the low educational attainment of Mexican immigrants underestimates their real skill and productivity. We cannot deny, however, that the low educational attainment of Mexican migrants also correlates with low annual and hourly wages, so that the economic returns to this (supposed) high level of innate skill and motivation is not easily detected in the Current Population Survey. Chiswick would argue that the respondents in the CPS (especially the Mexican immigrants) are weighted to the most recent immigrants (because the flow of immigration from Mexico has been increasing over time—see Table 3), and that it takes time for the

Table 3
Historical Trends in Legal Mexican Migration to the U.S.

Period	Number of legal Mexican Immigrants	Total (all countries) legal immigrants	Mexican immigration as % of Total
1901-1910	49,642	8,273,667	0.60%
1911-1920	219,004	5,763,263	3.80%
1921-1930	459,287	4,100,777	11.20%
1931-1940	22,319	531,405	4.20%
1941-1950	60,589	1,044,638	5.80%
1951-1960	299,811	2,519,420	11.90%
1961-1970	453,934	3,313,387	13.70%
1971-1980	640,294	4,509,113	14.20%
1981-1989	974,200	5,801,600	16.79%
1990	680,186	1,536,483	44.27%
1991	947,923	1,827,167	51.88%
1992	214,128	973,977	21.98%
1993	126,642	904,292	14.00%
1994	111,415	804,416	13.85%
1990-1994	2,080,294	6,046,335	34.41%

Note: From 1989–1994, 2.67 million persons, most of them of Mexican origin, received amnesty due to provisions or IRCA (1986) and were counted as new immigrants for those years.

innate skills of immigrants to lift their earnings to the level of native workers. Chiswick (1986) reports that the earnings of Mexican immigrants exceeds the earnings of native workers when the Mexican immigrants have been in the U.S. labor market for 15 years.

We have not considered migrants' possible effect on the U.S. economy through their consumer purchases. Migrants not only increase the size of the U.S. consumer market but they also have particular tastes and needs that may affect the tastes of natives. Immigrants, as Simon (1989) points out, have throughout history been viewed as the bearers of new ideas, new ideas that have been tested in other societies and contexts. Despite the fact that the effect of population growth on economic

growth is quite resistant to formal quantification because of the myriad ways that population increase can trigger economic effects, we believe that questions about economies of scale ought be considered more systematically. There is no sound reason to think that the U.S. has passed some magic population density that makes it immune to any further benefits from economies of scale. The implications of increasing returns to scale are simply that, other things being equal, a larger population will tend to increase the economic efficiency of the entire society.

Impacts of Migration

The U.S. Labor Market Impacts of Low-skill Migration from Mexico

*Paul S. Davies, Michael J. Greenwood, Gary L. Hunt, Ulrich Kohli & Marta Tienda**

Introduction

Although in recent years a growing literature has focused on the economic effects of U.S. immigration (Borjas, 1994; Greenwood and McDowell, 1986; LaLonde and Topel, 1997; and Smith and Edmonston, 1997), little research has dealt directly with the migrant group from Mexico. An example of this gap is a recent study of the economic consequences of U.S. immigration by the National Academy of Sciences (Smith and Edmonston, 1997) that makes only passing reference to the Mexico-born population. By estimating the U.S. employment and wage effects of this population, the present study takes a step toward filling this research gap.

Four distinctive characteristics of Mexican migrants to the United States have implications for the nature and magnitude of their labor market impacts. First, the

sheer volume of the migration flow and the size of the Mexico-born population in the United States set this foreign-born group apart. Second, a large share of the undocumented population is of Mexican origin. Third, the Mexico-born population in the United States has low education levels, which although improving have not kept pace with those of the U.S. population. Fourth, the Mexico-born population is highly concentrated in the Southwest and in several large cities.

Mexico contributes a larger share to the U.S. foreign born population than any other country—roughly as much as the entire continents of Asia and Europe. During 1994 alone the United States admitted as legal resident aliens 111,398 persons born in Mexico. Between 1989 and 1993, boosted by legalizations under terms of the Immigration Reform and Control Act of 1986 (IRCA), 2.4 million persons of Mexican birth were legally admitted to the United States. The size of the migrant flow is important for understanding impacts because arguments about scale economies and about magnitudes of impacts derive directly or indirectly from the volume of migration, depending, of course, on residential patterns, return migration rates, and other social and demographic characteristics we discuss below.

Not only is Mexico the single most important source of legal immigrants, it is also the primary source of unauthorized migrants. Data on undocumented migrants are necessarily sketchy. However, studies of legalization authorized by IRCA indicate that 70 percent of those who were legalized under the amnesty program were of Mexican origin (see Tienda, et al., 1991; Singer, 1994). Between 1989 and 1994, the U.S. Border Patrol located 6.4 million entries from Mexico who were deemed deportable. Legal status of migrants is important for understanding the impacts of Mexican migration because public attitudes and behavior toward migrants from Mexico are often driven by images, accurate or not, of undocumented migrants. Employers who fear sanctions for hiring migrants who entered the United States unlawfully may deliberately avoid hiring all workers who look and sound like foreigners. Such behavior could directly affect the employment and wage opportunities of earlier arrivals who entered legally, as well as some native residents who speak English with an accent or "look Mexican." Although these effects are difficult to quantify, there is little disagreement that the presence of a large share of undocumented migrants among the Mexican migrant population shapes the policy and social climate surrounding Mexican migration to the United States.

The Mexican migrant population comes to the United States with low levels of formal education. Male Mexican migrants average nine years of education, which is substantially less than most other native and migrant groups, who average a high school education. Because Mexico has been the single largest source of migrants to the U.S. for 30 years, and because migrants from Mexico have low levels of formal education, recent concerns about admitting immigrants with low skills have focused on migrant streams from Mexico. The skill composition of Mexican migrants

has important implications for a study of impacts because it is central for addressing questions about labor market impacts, and in particular, whether Mexicans compete mainly with other low wage workers (e.g., native-born teens, unskilled women, blacks, Mexican Americans, and migrants who arrived earlier), or whether Mexican migrants fill labor market niches that domestic and other foreign-born workers do not want. In light of recent trends in U.S. wage inequality between skilled and unskilled labor groups, the question of whether large numbers of unskilled Mexican migrants can be absorbed in the labor market remains a central source of controversy about the economic impact of Mexican migrants.

In 1990, of 13.5 million Mexican-origin persons enumerated in the census, 45.3 percent resided in California and 28.8 percent resided in Texas.[1] California's share of national population was 12.0 percent in 1990 and Texas's was 6.8 percent. Such concentrations of Mexican-origin population suggest highly regionalized immediate impacts of the migrants, although several studies suggest that the effects of immigrants are quickly arbitraged across the nation (Borjas, 1994). A major advantage of the approach adopted here is that for simulation purposes we are able to distinguish areas with differing concentrations of Mexico-born persons rather than relying only on nation-wide estimates of the impacts.

The wage and employment impacts of the foreign born on native workers may differ according to race and national origin, but the findings of prior studies are highly variable. The empirical evidence generally indicates that immigrant groups tend to be substitutes for some domestic labor market groups and complements for other domestic workers (Borjas, 1987a). Specifically, Hispanic immigrants appear to be substitutes for white domestic male workers, but complements with native Hispanic workers. Mexican immigrants have a small negative impact on the earnings of both white and black native-born men. However, all immigrants have a sizable negative impact on their own wage levels (Borjas, 1986a, and 1986b). One important implication of earlier studies is that in attempting to assess substitution and complementarity relationships among the foreign born and the native born, investigators should disaggregate the study population as much as possible. The functional form of the production function used in this study allows for the specification of considerably more labor types than is found in the typical production-theory approach (Greenwood, Hunt, and Kohli, 1996; 1997).

This study employs cross-sectional 1990 Census data on metropolitan areas in the context of a production-theory approach that uses the Symmetric Normalized Quadratic functional form and that incorporates eight labor inputs and a measure of capital. The eight labor inputs, whose estimation is allowed by the functional form employed here, permit us to account not only for low-skill Mexico-origin labor, but also for certain skill groups with whom this group is likely to compete in U.S. labor markets (including native, low-skill labor distinguished by sex, as well

as foreign-born, low-skill labor from parts of the world other than Mexico). The incorporation of capital into the empirical model avoids the assumption of separability of labor and capital that has been problematic in several earlier empirical studies. An advantage of cross-section data is that the model can be calibrated and simulated for specific metropolitan areas that differ in terms of their concentration of Mexico-born persons. Moreover, following the work of Greenwood and Hunt (1995), we incorporate into the model certain channels of influence in addition to the production channel. These other channels include labor force participation and aggregate demand.

Workers born in Mexico increase the supply of labor available in the United States. This increased labor supply clearly is not spread evenly across the United States, but rather is concentrated in proximity to the U.S.-Mexico border and in areas that offer those types of employment opportunities that are attractive to migrants from Mexico. Previous studies typically have shown that the wage and employment effects of increased immigration on native-born groups are not great (see Greenwood and Hunt, 1995; Greenwood, Hunt, and Kohli, 1996 and 1997). The largest impacts are on other foreign-born workers (like the immigrants themselves). The results of earlier studies, however, have been based on 1980 census data and on other data sources that are sufficiently old to throw into question their contemporary relevance. Moreover, the various studies that adopt a production function approach usually have not focused specifically on areas of high immigrant concentration.

In this paper, we disaggregate native workers by skill, gender, ethnicity, and nativity, and estimate the impacts of migrants from Mexico at the metropolitan area level in different regions of the U.S. including, especially, areas in the Southwest that are near to Mexico. We consider employment and wage effects stemming from both supply-side and demand-side effects of low-skill Mexican migration. Effects on the rental price of capital services also are explored.

Model Structure—An Overview

The model incorporates one aggregate output and nine inputs.[2] The relatively large disaggregation of inputs reflects the interest of this study in the effects of immigration by origin and skill level on native U.S. workers by skill level, gender, and ethnicity. Eight groups of labor are identified in the model: (1) native, low-skill, Mexican males; (2) native, low-skill Mexican females; (3) native, low-skill non-Mexican males; (4) native, low-skill, non-Mexican females; (5) native, high-skill males and females; (6) foreign-born, low-skill Mexican males and females; (7) foreign-born, low-skill non-Mexican males and females; and (8) foreign-born, high-skill males and females. The ninth input is capital. The methodology is the

same as that reported in Greenwood, Hunt, and Kohli (1997), but the labor inputs are different. In this part of the model substitution and complementarity relationships between the various inputs are estimated.

The model contains 18 endogenous variables. For each of the nine inputs, a factor price equation is specified by setting the factor price of the input equal to the input's value marginal product (VMP). The VMP for each input is derived from production theory as described below. Eight more behavioral equations are specified for the labor force participation rates of the eight groups of labor. These equations also are treated in more detail below, but their basic purpose is to measure the degree to which own-wage changes influence the labor force participation of the various labor groups. Finally, a behavioral equation for aggregate absorption of area output (i.e., area aggregate demand) is specified.

In addition to the 18 equations for the corresponding 18 endogenous variables, the model contains several technical relations, such as an aggregate value added production function and numerous identities. Some of these identities translate variables from their indexed forms used in theoretical specification (e.g., normalized employment), to their more policy-relevant forms (e.g., employment). The model contains 46 such technical relations and identities. Altogether the model contains 64 behavioral equations, technical relations, and identities.

Data

Because it facilitates our later presentation of empirical results, the next section discusses the 1990 data used in this study. This section is followed by a discussion of the model structure. The various components of the model's structure are followed by a discussion of issues relating to econometric estimation, as well as the presentation of the estimates obtained for model parameters.

Factor Inputs and Prices

The 1990 Public Use Microdata Sample (PUMS) of the U.S. Census (U.S. Bureau of the Census, 1992a) is used in the estimation of labor inputs and prices. The five percent (state) sample is used because it contains more observations than the one percent (metropolitan area) sample, while still containing metropolitan area of residence. A number of steps were taken in preparing these data. First, a random sample was drawn from the PUMS for the estimation of Mincerian-style earnings equations. Second, a skill-quantity variable was computed from the earnings equations for all individual observations in the five percent PUMS. This skill-quantity variable is important in making the demographic disaggregations described below. The third step involved aggregating the individual observations

to the Metropolitan Statistical Area (MSA) level to form aggregate area labor inputs and prices. Altogether 273 MSAs are identified from the 1990 PUMS five percent sample. As part of this third step, individual observations were grouped into eight demographic groups based on male/female, Mexican/non-Mexican, native-born/foreign-born, and high skill/low skill status. The criteria for assigning skill level are discussed below.

Earnings Equations

In preparing the data for estimation of earnings equations, a 10 percent random subsample of the five percent PUMS was taken. This was done following the subsampling procedures described in the PUMS Technical Documentation (U.S. Bureau of the Census, 1992b). Only those observations satisfying the following criteria were used: age between 16 and 65, not currently in school, not currently in the military, not self-employed, and 1989 earnings greater than zero. This process yields a national subsample of 456,202 observations.

Using this national subsample, Mincerian-style earnings equations were econometrically estimated separately for males (235,069 observations) and females (221,133 observations). For these earnings equations, an hourly wage variable was created by dividing 1989 earnings by hours worked in 1989 (computed as hours worked per week times weeks worked in 1989). The natural logarithm of the 1989 hourly wage served as the dependent variable.

The independent variables included: educational attainment, potential labor market experience (constructed as age less education less six) and its square, a dummy for metropolitan area residence, race and ethnicity dummies, a foreign-born dummy and its interaction with year of entry dummies, a set of census division dummies, a set of world region of origin dummies, a set of occupation dummies, and a set of industry dummies.

The OLS estimates produce reasonable results. For both males and females, the log of hourly earnings increases with education. It also increases with potential labor market experience, but at a decreasing rate. Foreign-born individuals have log-wages below those of natives, although this effect is not statistically significant. The adjusted-R^2 in the male earnings equation is 0.365 and that in the female equation is 0.252. The equation F-value for males is 2759.75 and for females is 1524.22.

Skill Quantity

Based on the results of the earnings equations, we predicted a "skill-quantity" variable or skill index for all individuals in the subsample. This skill index was

predicted using the estimated coefficients on educational attainment, potential labor market experience and its square, the foreign-born dummy and the interactions between foreign-born and year of entry, and the world region of origin dummies, along with the actual values of each of these variables for each individual in the subsample. This predicted skill-index variable is designed to reflect skill quantity (a proxy for human capital) rather than various aspects of "skill price" such as racial or ethnic discrimination or compensating differentials due to industry, occupation, region of residence, or MSA residence. The skill-quantity estimates are made separately for males and females using the estimated coefficients from the appropriate regression equation.

Each individual in the subsample was coded as being in one of four skill quartiles by ranking all observations by predicted skill quantity and splitting them into four groups of equal size. Each individual was then designated as low skill or high skill depending on how the skill quartiles are grouped. In the analysis conducted in this paper, the lower two skill quartiles are designated as "low skill" whereas the upper two skill quartiles are designated as "high skill." This low skill/high skill segmentation is discussed further below.

Aggregation

Having created the skill quartiles from the earnings equations, we next aggregated the data to the MSA level. To do so, we used the complete five percent 1990 PUMS rather than the subsample used for the earnings equations. Observations were excluded from the data if they did not meet our "selection criteria." The skill-quantity variable was computed for all individuals as described above. The individuals were then coded as belonging to one of the four skill quartiles based on the value of this skill quantity variable and the quartile "break-points" determined from the 10 percent national subsample.

As indicated above, eight demographic groups were created for the Mexican model. Individuals were coded as native-born if they were born in the U.S. or in U.S. outlying areas (e.g., Guam, American Samoa, Puerto Rico). Otherwise, individuals were coded as foreign- born. Individuals were considered to be low-skill if they were in the lower two skill quartiles. The upper two skill quartiles accounted for high-skill individuals. Mexican status is conferred by birth in Mexico for the foreign-born and by Mexican origin (as reported on the PUMS Hispanic origin question) for the native born.

For each demographic group, several variables were created at the MSA level. These include total group population, number employed in the group, group labor force participation rates, total group earned income, total group non-labor income, total group welfare income, total group social insurance income, and total group

hours worked. Furthermore, aggregate MSA population, employment, earnings, and non-labor income were created by summing across all eight demographic groups. The eight demographic groups exhaustively include area population, and therefore employment, earnings, and non-labor income.

This aggregation process was conducted MSA-by-MSA, in all states plus the District of Colombia, yielding 273 MSAs. Ten of these 273 cross state boundaries, and therefore represent the combination of data from multiple states. After deleting those MSAs in which one or more of the eight demographic groups have small or zero populations, we are left with 122 useable MSAs for the analysis conducted below.

Model Structure

Production Function and Factor Prices

We assume that in each metropolitan area, the technology can be represented by an aggregate production function. Let y be the quantity of output and assume J inputs,[3] the quantities of which are denoted by x_j. The production function is written as follows:

$$(1)\quad y = f(x_1, \ldots, x_J).$$

This function is assumed to be twice continuously differentiable, increasing, quasiconcave, and linearly homogeneous. Under profit maximization, we get the marginal product conditions (also known as the inverse input demand equations, or the wage equations) by differentiation:

$$(2)\quad \frac{w_j}{p} = \frac{\delta f(\cdot)}{\delta x_j}, \quad j = 1,\ldots, \ J,$$

where p is the price of output and w_j is the price of the j^{th} input.

To describe the substitution and complementarity relationships between the J inputs, we can use the Hicksian elasticities of complementarity[4]:

$$(3)\quad \psi_{j,k} \equiv \frac{f\, f_{j,k}}{f_j f_k}\ , \quad j,k = 1,\ldots, \ J,$$

where $f_j \equiv \delta f(\cdot)/\delta x_j$, $f_{j,k} \equiv \delta^2 f(\cdot)/(\delta x_j \delta x_k)$, and $f \equiv f(\cdot)$.

Quasiconcavity of the production function implies that $\psi_{j,j} \leq 0$. Furthermore $\psi_{j,k} > 0$ if inputs j and k are Hicksian q-complements, and $\psi_{j,k} < 0$ if inputs j and k are Hicksian q-substitutes.

The Hicksian elasticities of complementarity may seem to be somewhat difficult to assess, and it is sometimes more convenient to use quantity elasticities of inverse demands. These are defined as follows:

$$(4)\quad \eta_{j,k} \equiv \frac{\delta \ln w_j}{\delta \ln x_k}$$

Making use of Equations (2) and (3), one can easily show that:

$$(5)\quad \eta_{j,k} = \psi_{j,k} \cdot s_k,$$

where s_k is the cost share of the k^{th} input: $s_k \equiv x_k w_k /(py)$.

To describe the production function, we use the Symmetric Normalized Quadratic functional form introduced by Diewert and Wales (1987). It is as follows:

$$(6)\quad f(\cdot) = \sum_j a_j x_j = \frac{1}{2}\frac{\sum_j \sum_k b_{jk} x_j x_k}{\sum_j \beta_j x_j}$$

where $b_{jk} = b_{kj}$, $\sum b_{jk} = 0$, $\sum \beta_j = 1 \quad (j,k = 1,...,J)$. As shown by Diewert and Wales (1987), this functional form is flexible, and it is globally concave as long as $B \equiv [b_{jk}]$ is negative semidefinite and $\sum \beta_j w_j > 0$. The negative semidefiniteness of B can be imposed by using the reparameterization of Wiley, Schmidt, and Bramble (1973). That is, we set $B = -TT$ where $T \equiv [\tau_{jk}]$ is a lower triangular matrix. As to $\sum \beta_j x_j$, this term can be interpreted as a Laspeyres input quantity index.

Assuming cost minimization, the inverse input demand functions are obtained by differentiation:

$$(7)\quad \frac{w_j}{p} = a_j + \frac{\sum_k b_{jk} x_k}{\sum_k \beta_k x_k} - \frac{1}{2}\beta_j \frac{\sum_k \sum_m b_{km} x_k x_m}{(\sum \beta_k x_k)^2}, \qquad j = 1, \ldots, J.$$

One difficulty with flexible functional forms is that their number of parameters increases very rapidly with the number of inputs. Even if one assumes linear homogeneity, the number of parameters in a *N*-input model is equal to $N + (N - 1) N / 2$. Thus, if $N = 2$, the number of parameters is 3; if $N = 4$, there are 10 parameters, and if $N = 16$, the number of parameters jumps to 136. This may lead to serious problems of multicollinearity, and it may lead to inefficient estimates. One way around this problem has been suggested by Diewert and Wales (1988),

who introduce the concept of *K*-flexibility, or semiflexibility. A functional form $g(z)$ is said to be semiflexible at some point z^* if it has enough free parameters for $g(z^*)$, its gradient $\nabla g(z^*)$, and its Hessian $\nabla^2 g(z^*)$ to attain arbitrary values, provided that $\nabla^2 g(z^*)$ is restricted to have rank $K < N$. A semiflexible functional form therefore has less parameters than a flexible one, and, although it is not flexible, it does not impose any obvious *a priori* restrictions on the size or the signs of the elasticities of substitution or complementarity.

The concept of semiflexibility rests on some new results obtained by Diewert and Wales (1988). They show that any semi-definite $N \times N$ matrix of rank *K*, where *K* is less than the maximal possible rank *N*, has a *K*-column triangular decomposition. This means that $T \equiv [\tau_{mn}]$ is now such that $\tau_{mn} = 0$ for $1 \leq m < n \leq N$ and for $n = K + 1, \ldots, N$. Thus, *T* now is defined as a lower triangular $N \times N$ matrix which has zeros in its last $N - K$ columns. Note that *T* now has only $N(N + 1)/2 - (N - K)(N - K + 1)/2$ free parameters. This may mean a substantial reduction in the number of parameters to be estimated. Thus, if $N = 8$ and $K = 3$, the number of free parameters is 21, as opposed to 36 in the unrestricted case. This reparameterization applied to *B* in (6) yields the *K*-flexible—or semiflexible—version of the Symmetric Normalized Quadratic production function. In what follows, we will set $K = 3$; indeed, there is ample evidence that there is little to be gained in considering larger values of *K*.[5]

For empirical implementation the factor price equations have to be imbedded within a stochastic framework along with the other behavioral equations. We assume that the inverse input demand equations are stochastic due to errors in optimization. We define the optimization errors in the input demand equations at time *t* as $v_j(t)$ $(j = 1, \ldots, J)$. We assume that the vector of disturbances is identically and independently, joint normally distributed with mean zero and non-singular covariance matrix Ω:

$$(8) \quad E[v(t)v(s)] = \begin{cases} \Omega \ \ \forall\, s,t \ \ if \ \ s = t \\ 0 \ \ if \ \ s \neq t, \end{cases}$$

where Ω is a $J \times J$ positive definite matrix.

The model is estimated by the algorithm of Berndt, Hall, Hall, and Hausman (1974) which is essentially a nonlinear version of the iterative Zellner (1962) method. All estimations were done on a Digital AXP 3000-800S computer, using SHAZAM,[6] version 7.0. The nine inputs of the model are identified above.

Parameter estimates are shown in Table 1. Concavity is imposed globally, and it is therefore satisfied for all observations. Monotonicity is satisfied for all observations but one. Table 2 reports estimates of the Hicksian elasticities of complementarity (ψ_{jk}) at the sample mean, whereas Table 3 gives the sample-

The subscripts refer to the inputs which are defined as follows:
(1) Native, low-skill, Mexican, male labor; (2) Native, low-skill, Mexican, female labor; (3) Native, low-skill, non-Mexican, male labor; (4) Native, low-skill, non-Mexican, female labor; (5) Native, high-skill labor; (6) Foreign-born, low-skill, Mexican labor; (7) Foreign-born, low-skill, non-Mexican labor; (8) Foreign-born, high-skill labor; (9) Capital.

mean values of the quantity elasticities of inverse input demands (η_{jk}). Capital is a Hicksian complement for all categories of labor, except foreign-born high-skill labor. Overall, however, and this is rather surprising, there appears to be far more substitution than complementarity relationships.

Most labor categories seem to be competing with each other. The strongest complementarity links are between native, low-skill men and low-skill migrants, as well as between native, low-skill, non-Mexican women and high-skill migrants. Judging from the elasticities shown in Table 3, an increase in the number of low-skill Mexican migrants would tend to benefit capital and low-skill native males, and hurt all other categories of labor; however, except for low-skill Mexican migrants themselves, these effects are very small.

Labor Force Participation

The modeling of labor force participation rates begins with a reservation wage equation and a market wage equation:

Table 2

j=9	0.001	0.006	0.007	0.043	0.101	0.006	0.005	-0.003	-0.167

The subscripts are defined at the bottom of Table 1.

(9) $S = \gamma_0 + \gamma_1 H + \gamma_2 Z + u_1$

(10) $W = \beta_0 + \beta_1 X + u_2$

where S is the reservation wage (or shadow wage), H is hours worked, Z is a vector of other factors that influence the reservation wage, W is the market wage, and X is a vector of factors that influence the market wage. The gammas and betas are parameters. The u_1 and u_2 terms are zero mean, spherical, normally distributed stochastic errors. Equations (9) and (10) apply to individuals.

Let $\overline{W} = \beta_0 + \beta_1 \overline{X},$ where a bar over variables denotes a mean. Therefore,

(11) $W = \beta_0 + \beta_1 X + \overline{W} - \overline{W} + u_2,$

which implies

(12) $W = \beta_1 (X - \overline{X}) + \overline{W} + u_2.$

Assuming that W=S, Equations (9) and (10) can be equated and the following equation for hours can be derived:

(13) $H = \{[\beta_1 (X - \overline{X}) + \overline{W} - \gamma_0 - \gamma_2 Z]/\gamma_1\}.$

If H>0, then the individual participates. If H≤0, then the individual does not participate.

For participating individuals, H>0 implies that Eq.(13) becomes

(14) $\{[\beta_1 (X - \overline{X}) + \overline{W} - \gamma_0 - \gamma_2 Z]/\gamma_1\} + \{[u_2 - u_1]/y_1\} > 0.$

Equation (14) in turn implies the following:

(15) $\{[u_2 - u_1]/\gamma_1\} < \{[\beta_1 (X - \overline{X}) + \overline{W} - \gamma_0 - \gamma_2 z]/\gamma_1\}.$

Therefore, for participants, H>0, we have

(16) $u_2 - u_1 < \beta_1 (X - \overline{X}) + \overline{W} - \gamma_0 - \gamma_2 z.$

This implies that the probability of participating is

$$(17)\ \Pr ob(H > 0) = \Phi\{[\beta_1(X - \overline{X}) + \overline{W} - \gamma_0 - \gamma_2 z]/\sigma\}$$

where sigma is the standard deviation of $u_2 - u_1$. Each of the eight labor groups has a corresponding Equation (17) structure to represent its labor force participation rate behavior.

The sources of data used to estimate the participation rate equations for each of the eight labor groups are those described above for the labor quantity and price variables and the aggregate area output price variable. Specific variables utilized from the five percent PUMS include a labor force participation dummy variable as the dependent variable; and the following independent variables in the vector X (see Eq. (17)): white, black, years of schooling completed, potential experience and its square (as defined above), foreign-born dummy variable, and immigration cohort 1980-90. The vector Z (see Eq. (17)) contains the following independent variables: family income, black, white, number of children under six years of age present in the household, and number of children six to seventeen years of age present in the household. All income variables, including the average area wage for the labor group, are expressed in real terms by deflating by the aggregate area output price variable described above.

The stochastic assumptions made for the labor force participation rate equations flow from the theoretical discussion presented above. Each of the eight labor group's participation is modeled as a binary probit process. The maximum likelihood estimates of the probit equations for the eight labor groups are presented in Appendix Tables A1 through A8. It is notable that the estimated coefficients on the area average real wage for seven of the eight labor groups are positive and significant. The estimated effect of higher real wages on average is negative and significant only for the group of native, high skill persons.

Each estimated equation contains both area average variables and variables that represent deviations of individual observations from the area averages. The theoretical motivation for this structure is presented above. The deviations are represented by variable names beginning with the letter "D." The variable names in Appendix Tables A1 through A8 are associated with the following variables: AREARW, area real wage of group; RFAMINC, real household income of group; KIDLT6 and KID617, children less than six years of age in household and those between 6 and 17 years of age in household, respectively; BLACK and WHITE, dummy variables representing broad race of individuals; ED, years of schooling completed; X and XSQ, years of potential experience and its square, respectively; IMG8090, immigrant dummy variable interacted with entry cohort of 1980-90. In

each of the eight corresponding tables of estimates, the marginal effects of each independent variable on the probability of participating (=1) or not participating (=0) is presented.

Aggregate Output Quantity and Price

Our methodology requires an index of real output (real value added). Let x_j^h and w_j^h be the quantity and the price of input *j* in region *h*. We first define $\tilde{w}_j$ as the mean price of input *j* across all regions:

$$(18)\ \tilde{w}_j \equiv \frac{\sum_h w_j^h x_j^h}{\sum_h x_j^h}$$

We next define s_j^h as the value-added share of input *j* in region *h*:

$$(19)\ s_j^h \equiv \frac{w_j^h x_j^h}{\sum_j w_j^h x_j^h}$$

We also define $\tilde{s}_j$ as the mean value added share of input *j*, that is the share of input *j* in the total of the value added by all regions:

$$(20)\ \tilde{s}_j \equiv \frac{\sum_h w_j^h x_j^h}{\sum_h \sum_j w_j^h x_j^h}.$$

The price of output in region *h* (p^h) is then calculated as a Tornqvist price index, where the prices in region *h* are compared to the corresponding mean prices:

$$(21)\ p^h = \exp\left[\sum_j \frac{1}{2}(s_j^h + \tilde{s}_j)\ln\frac{w_j^h}{\tilde{w}_j}\right].$$

Finally, the quantity of real value added in region *h* is obtained implicitly as:

$$(22)\ y^h = \frac{\sum_j w_j^h x_j^h}{p^h}.$$

The data used for the labor input quantities and prices are those discussed above. The data used to compute the quantity and price of capital services are a combination of the labor data and gross state product data obtained from the Bureau of Economic Analysis' *Regional Economic Information System (REIS) and a Jorgensonian measure of the cost of capital.* The gross state product data

for each state were scaled to corresponding MSA-level data using one-digit SIC labor earnings at the state and MSA levels. The computation of the rental income for capital then was computed as the difference between MSA value added (i.e., gross product) and labor earnings. The rental price of capital services was estimated as the Jorgensonian user cost of capital services. Division of the rental income by the user cost yielded the estimate of the quantity of capital services used in this study.

The approach taken in Greenwood and Hunt (1995) is taken in specifying the absorption equation. The aggregate demand for real value-added output produced in area h is:

$$(23)\ \ln(y^h) = \alpha_0 + \alpha_1 \ln(p^h) + \alpha_2 \ln[Y^h/(N^h p^h)]$$

where y^h is aggregate demand for real value-added output produced in area h^h, p^h is the corresponding aggregate price index, N^h is area population, Y^h is area household income, "ln" is the natural logarithm operator, and the alphas are parameters. Equation (23) can be expressed in inverse form by solving for $\ln(p^h)$.

The aggregate area output price and quantity variables are those defined above. Aggregate area household income and population are computed from the summation of the corresponding area aggregate group variables across the eight demographic groups delineated above.

In this study, instrumental variables estimation is not entertained. Based on the work of Greenwood and Hunt (1995), the estimation of the aggregate absorption equation requires instrumental variables to obtain the correct sign on the price coefficient. Therefore, the estimates from Greenwood and Hunt (1995) are used in this study with appropriate scaling.

Model Simulations

The model is organized into six blocks of equations: (1) production; (2) labor force; (3) input value shares; (4) income; (5) absorption; and (6) add factors. Block 1 consists of 11 equations. Nine represent the value marginal product equations for each of nine inputs: five categories of native labor, three categories of immigrant labor, and capital. The skill levels are defined as quartiles of the U.S. distribution of skills. The value marginal products are set equal to wage rates (i.e., skill prices). The value added production function is the tenth equation in the first block. The eleventh equation is for aggregate value added output in nominal terms. All of these variables are index numbers. The indexing procedure is discussed below.

Block 2 consists of 33 equations. There are eight labor force identities, one for each of the eight labor groups. These specify labor force size as the product of labor force participation rate and population of labor force age. Eight employment identities define a normalized (i.e., indexed) employment measure, described below, for each of the eight labor groups, and eight additional employment identities for the employment of each of the eight groups of labor. Each of the eight labor groups also has a labor force participation equation specified for it. Finally, there is an identity for aggregated population of labor force age, the sum of the corresponding variable across the eight groups.

Block 3 consists of nine input value share equations, one for each of the eight labor inputs and capital. Block 4 includes an aggregate income identity: the sum of labor earnings and nonlabor income; and it includes eight wage rate equations (actual wage rates and not index numbers). Block 5 consists of an absorption equation written in inverse form so that the area price index is on the lefthand side.

Block 6 consists of 18 equations, one for each of the model's add factors. The add factors are variables that are computed endogenously during the baseline simulation of the model to ensure that the baseline simulation solution values equal the observed sample values. There is an add factor for each structural/behavioral equation in the model. Add factors are not required for identities since the computed values for the corresponding variables will equal the observed sample values if the structural/behavioral variable values are forced (by add factoring) to equal the observed sample values. There are eight add factor equations for the eight labor force participation rate equations. There are nine add factor equations for the value marginal product conditions. Finally, there is an add factor equation for absorption.

The model simulations were accomplished in two steps. The first step was to generate an add-factored baseline simulation. The second step was to increase the "foreign-born, low-skilled, Mexican" labor group by 20 percent in each of the 122 metropolitan areas. Our basic assumption here is that Mexico-born migrants in the United States tend to have relatively low skill levels because, as noted above, they tend to have relatively low levels of education. The difference in the solution values of each of these two steps, in each area, represents our simulated impacts of a 20 percent increase in low-skilled, Mexican migrants.

All blocks of the model are "turned on" in the simulations. Consequently, both supply and demand-side effects on employment and real factor prices are captured. In order to understand the economics of the simulations, it is useful to disaggregate conceptually the simulations into three parts. In the first part, only the effects of immigration on the value marginal products of each input and on output are considered. Consequently, increased immigration results only in factor price effects and an output effect. Only the production block of the model is therefore "turned

on." Consequently, impacts are limited to those operating through the production structure channel of influence.

In the second part, employment effects in addition to factor price effects are considered. This is accomplished by "turning on" the production, labor force, input value shares, and income blocks of the model structure. Impacts are therefore limited to those operating through the production structure and labor force participation channels of influence.

Additional effects are "turned on" in the third part by considering aggregate demand in addition to the effects occurring through the production structure and labor force participation channels. The aggregate demand effects have two aspects. First, the impacts of changes in local wage and nonlabor income on local demand are incorporated. If the sum of changes in local wage and nonlabor income is positive due to immigration, then local demand will rise and the local price level will be supported. Second, the effects of changes in output on the local price level are incorporated. An increase in migration directly results in an increase in labor input locally and therefore to the production of more local output. If the labor force participation effects across all labor groups do not offset this positive direct output effect of increased migration, the level of locally produced output will rise. In parts one and two, such an output increase would be absorbed without a change in the price of locally produced output. In this way, the other two parts represent, by assumption, the operation of a small open economy. In this third part, local price is endogenized and a lower price of local output will be required to get the extra output absorbed, *ceteris paribus*.

Aggregate demand effects operate in two opposing directions on the local price level and therefore on value marginal products. If the local demand effect bolsters the local price level, then this will support value marginal products and factor prices. However, this positive effect could be offset to some extent, or outweighed, by the downward pressure on local price by any extra local output produced with increased immigration. In the simulation of the model, of course, both effects are computed, and the result for factor prices is incorporated. The simulation results presented below incorporate all three of these parts: the production structure channel of influence, the labor force participation channel, and the aggregate demand channel.[7]

In Table 4, the simulated effects on the real wages of the eight groups of labor are presented. For all 122 areas, the average real wage of the migrant group itself falls by 3.0 percent. As shown in Table 5, due to this lower wage rate, workers in this category withdraw from the labor force, so that ultimately employment of this group increases by 19.39 percent and not by 20 percent, which reflects a displacement effect of about 0.6 percent (20.0 percent - 19.4 percent). The wage rates of other labor categories are almost unchanged. For example, native, low-skill females of Mexican ancestry suffer a wage loss of only about 0.3 percent

Table 4

Percentage Change in Real Wage of Various Labor Skill Groups Due to a 20-Percent Increase in Low-skilled, Foreign-born Mexican Labor—Selected MSAs

and their employment falls by about 0.2 percent. Thus, for the average U.S. region, even relatively large increases in Mexican-born labor do not appear to have large impacts on native workers.

Metropolitan areas in California and Texas have relatively heavy concentrations both of Mexican-born persons and of native-born persons of Mexican ancestry. Each of these states contains 23 metropolitan areas in the sample. The major impact of a 20-percent increase in foreign born, low-skill Mexican labor in California is on this group, whose wages fall by 6.9 percent (Table 4) and whose employment declines by 1.3 percentage points (20 percent less 18.7 percent) (Table 5). The largest wage impacts on other groups occur to foreign-born, low-skill, non-Mexicans and to foreign-born, high-skill persons, but in each case the effects amount only to about one percent. The labor displacement effect is never more than 0.5 percent for any group (Table 5).

The results for Texas are similar to those for California, but for the most part are slightly more moderate. For example, when their employment is increased by 20 percent, foreign-born, low-skill Mexican workers in Texas suffer a 5.0 percent wage decline (Table 4) and about 1.1 percentage point job displacement (Table 5). Comparable effects for Arizona, New Mexico, and Colorado (11 areas) are a 3.7 percent wage reduction and approximately 0.8 percent displacement. Areas of high concentration of foreign-born, low-skill Mexican workers clearly experience the largest impacts of a 20-percent increase in this labor category. For 13 areas for which this labor group constitutes 60 percent or more of the foreign-born population, the wage effect for a 20-percent increase in this group represents a decline of 11.4 percent. Employment of the group is reduced by 2.4 percentage points. Native, low-skill females of Mexican ancestry suffer a 1.3 percent wage decline and a 0.4 percent job displacement effect. Even these last effects are not large.

Three possibilities have been suggested for the repeated empirical finding that the effects of even relatively large increases in foreign-born labor do not appear to have great impacts on native workers. First, the foreign-born population is a relatively small fraction of the population and the labor force, and thus the effects may not be detectable. The results presented above suggest that even in areas with heavy concentrations of foreign-born, low- skill, Mexican labor, the wage and employment displacement effects of relatively large increases in this labor group are not great either for the native-born groups or for other foreign-born groups. The only noteworthy impact is on the own-wage rate because the members of the group are very good labor market substitutes for one another. A second possible explanation for the relatively small impacts of the foreign born on wages and employment is that offsetting increases occur in labor demand and supply relationships with the effect that the wage changes tend to cancel. A third explanation is that efficient U.S. markets result in the effects quickly arbitraging themselves across the nation, with the result that the effects are difficult to detect.

A closer examination of specific metropolitan areas in California and Texas and of other areas of high foreign-born, low-skilled Mexican concentration, indicate that the simulated wage and employment effects vary substantially. For example, among metropolitan areas in California, the own-wage reduction resulting from the 20-percent increase in foreign-born, low-skilled Mexican workers reaches as high as 15.2 percent in Visalia-Tulare and as low as 0.24 percent in Redding (Table 4). Employment of foreign-born, low-skilled Mexicans is reduced by as much as 3.1 percent in Los Angeles and as little as 0.04 percent in Redding (Table 5).

Similar variation in the magnitude of wage and employment effects is apparent among metropolitan areas in Texas. The wage reduction experienced by foreign-born, low-skilled Mexicans varies between 25.4 percent for McAllen-Edinberg-Mission and 0.5 percent for Beaumont (Table 4). The group experiences employment reductions of between 6.1 percent in McAllen-Edinberg-Mission and 0.1 percent in Beaumont (Table 4). Also of note, wages of foreign-born, low-skilled Mexicans fall by 15.9 percent in Yuma, Arizona, while employment falls by 3.4 percent. Greeley, Colorado, also has a high concentration of foreign-born, low-skilled Mexicans, although the own-wage reduction there is only 3.2 percent and the employment reduction is just 0.6 percent.

The range of the wage and employment effects on other groups resulting from a 20-percent increase in foreign-born, low-skilled Mexican workers is much smaller. Among metropolitan areas in California, the wages of native, low-skilled males (both Mexican and non-Mexican) increase, though this increase is relatively small and varies between 0.0 percent in Redding and 2.3 percent in Los Angeles (Table 4). The wage effect is similar for metropolitan areas in Texas, reaching a high of 4.3 percent in McAllen-Edinberg-Mission. The employment effect on this group varies little across metropolitan areas in California and Texas and is nearly zero in most cases.

To the extent that wages and job opportunities of the native born are influenced by low-skill migrants from Mexico, females and especially Mexican ancestry females bear the impacts. However, these effects are not great even in areas with high concentrations of foreign-born, low-skill Mexicans. For example, in areas where at least 60 percent of the foreign-born population consists of low-skill migrants from Mexico, a 20 percent increase in this population reduces the real wage of native-born Mexican ancestry females by 1.3 percent and their employment by 0.4 percent (Tables 4 and 5).

As discussed above, native, low-skilled females (both Mexican and non-Mexican) and other foreign-born groups tend to suffer wage and employment decreases as a result of the 20-percent increase in foreign-born, low-skilled Mexican workers. Although the effects are quite small on average for metropolitan areas in California and Texas (around 1 percent or less), some areas of high foreign-born, low-skilled Mexican concentration display relatively large effects. For example, in

Los Angeles, California, the wages of foreign-born, high-skilled workers fall by 3.4 percent while employment falls by 0.8 percent. In McAllen-Edinberg-Mission, Texas, the wages of native, low-skilled, Mexican females fall by 4.0 percent, accompanied by a 1.3 percent reduction in employment.

A general presumption is that the two groups most likely to enjoy benefits due to migration from Mexico to the United States are the migrants themselves and their U.S. employers. However, because most models that focus on the U.S. impacts of immigration assume separability of labor and capital, as well as not incorporating capital explicitly in the empirical framework, empirical models typically do not allow any assessment of the returns to capital. In the model described above, we explicitly introduce capital and therefore we are able to perform simulation exercises that relate to the return to capital.

Table 6 reports the percentage change in the real rental price of capital due to a 20-percent increase in foreign-born, low-skilled Mexican labor. Among all of the inputs, capital is the clearest winner. In California areas in general the real rental price of capital increases by 0.82 percent, but the increases are somewhat larger in agricultural areas like Merced (1.7 percent), Salinas (1.7 percent), and Visalia-Tulare (1.4 percent). However, the largest increase (2.5 percent) occurs in Los Angeles. The average increase in the real rate of return to capital in Texas is 0.3, but for many areas close to the border the return is considerably higher (Brownsville—1.4 percent; El Paso—1.6 percent; McAllen-Edinberg-Mission—1.8 percent). Another border area that experiences a large increase in the rate of return to capital is Yuma, Arizona (1.7 percent). These results provide confirmation that the U.S. owners of capital benefit due to low-skill migration from Mexico.

Conclusions

In summary, labor market impacts are the most intensively studied effects of the foreign born in the United States. Although these effects may be mitigated or reinforced through less-highly studied channels of influence, the following conclusions have the strongest support. First, in both 1980 and 1990 the foreign born had a tendency to put downward pressure on the wage rates of the native born and a tendency to displace them from their jobs, but the effects were not large at the national level. The Mexican-born had similarly small impacts at the national level. Second, the foreign born are highly concentrated regionally, and although internal migration and trade tend to distribute the consequences over broader regions, the economic consequences also are concentrated. The largest impacts of low-skilled migration from Mexico are on other low-skilled migrants from Mexico, because the two groups are good labor market substitutes. In areas of high concentration of new migrants from Mexico, such as El Paso, other migrants from Mexico suffer

job displacement and significant downward pressure on their wage rates. Such effects impede the upward economic mobility of less-skilled migrants themselves. Finally, owners of capital and land are the primary U.S. beneficiaries from the presence of less-skilled migrants from Mexico.

Based on our econometric results the most surprising finding is probably that Hicksian complementarity relationships are much fewer than one might have expected. One tends to think that an increase in the supply of one factor increases the marginal products of the other factors. Indeed, one common argument in favor of immigration often is that more low-skill immigrants would make most other factors more productive, even if previous low-skill immigrants unavoidably get hurt. On average, Hicksian cross-elasticities of complementarity tend to be positive. Actually, they *must* be positive in the two-input case. They will also be positive, even if there are many inputs, if the functional form is Cobb-Douglas or CES, for instance. Yet, our results indicate that, even though capital is definitely a Hicksian complement for labor, Hicksian substitution relationships by far dominate among the different categories of labor. In the model, some complementarity relationships between various labor categories are evident, but they tend to be scarce and weak. These often involve low-skill native males and females, high-skill native females, and low- and high-skill migrants. As far as an increase in low-skill immigration is concerned, the clear winner is capital, but low-skill males and high-skill females are also likely to benefit.

The simulation results indicate that the largest adverse impacts of additional low-skilled, Mexican migrants falls on low-skilled, Mexican migrants themselves. Although small relative declines and advances are observed in the real wages and employment of other labor groups, the size of these effects is usually small. Capital's real rental price rises in the simulations, with the magnitude varying directly with the concentration of low-skilled, Mexican migrants in the various areas, as does the absolute value of the negative real wage effects on the migrants themselves and the various impacts on the labor market outcomes of other labor groups. These findings highlight the importance of demographic and geographic disaggregation in immigrant impact analyses.

Relative to other foreign-born groups and relative to the native born, persons born in Mexico have relatively low rates of U.S. internal migration (Greenwood, Henning and McDowell, 1997). Indeed, the native born of Mexican ancestry have low rates of internal migration in general. For example, among those household heads born in Mexico who entered the United States between 1970 and 1974, only 4.1 percent made an interstate move between 1985 and 1990. During the same period 5.2 percent of native-born heads of Mexican ancestry made such a move. In contrast, the same entry cohort from other countries of origin had much higher rates of internal migration over the 1985-1990 period. Representative rates of internal migration for these other groups are as follows: Philippines—12.3 percent;

Germany—18.0 percent; United Kingdom—19.7 percent; India—21.7 percent; Korea—15.8 percent; and Vietnam—15.2 percent. Among these countries, only for Mexico do the foreign born have lower rates of internal migration than the native born of each respective ancestry.

Neuman and Tienda (1994) also confirmed that undocumented migrants from Mexico are less likely to move across state lines than undocumented migrants from other regions. An analysis of administrative records (Legalization Application Processing System, or LAPS) revealed that just over one-quarter of amnestied immigrants changed residence at least once between the time of most recent entry and application for amnesty, but the likelihood of inter-state moves as undocumented migrants varied by place of birth. Mexicans were least likely to move subsequent to their initial entry, whereas Asians and Africans were most likely to do so. Specifically, only 19 percent of undocumented Mexicans who applied for legal status had moved across state lines before soliciting amnesty compared to over two-thirds of undocumented migrants from Asia and Africa, and over half of undocumented migrants from other Latin American countries (except Salvadorans, whose inter-state migratory behavior was similar to that of Mexicans).

If secondary migration leads to greater residential dispersion throughout the country, the social impacts of undocumented migration ultimately will be less severe in the states that serve as gateways for initial entry. Overall, unauthorized Mexican migrants who moved across state lines were less residentially concentrated at the time of application for amnesty than were nonmovers. For Mexicans, California and Texas were the main gateways for unauthorized entry. However, limited evidence suggests dispersal of impacts through inter-state moves of unauthorized Mexican migrants; nonmovers were more than twice as likely as movers to have entered through California (three out of four nonmovers from Mexico entered through California compared to just over one-third of movers). Mexicans who entered without inspection through Texas were more likely to have changed their state of residence by the time of application for amnesty, thereby attenuating impacts in this state. Specifically, just over half of Mexican movers entered through Texas compared to more than one-fifth of nonmovers.

These low rates of internal migration among persons born in Mexico are due to many factors, such as relatively low levels of education, lack of English language skills, and strong ties to areas with high concentrations of persons born in Mexico. Like education, migration is a form of investment in human capital and as such migration presumably yields higher future returns. Historically, internal migration has been a mechanism through which Americans have taken advantage of employment and wage opportunities elsewhere to improve their economic status. Thus, the low internal migration rates of both those born in Mexico and those born in the United States of Mexican ancestry may restrict their access to areas that

provide favorable economic opportunities. Lack of internal mobility also perpetuates high concentrations of the Mexican-born population. The continued entry of migrants from Mexico who are good labor market substitutes for earlier migrants results in continued job competition between the groups, which in turn restricts wage growth for them.

Notes

* This paper was prepared with support from the United States Commission on Immigration Reform—Mexico-United States Binational Migration Study. We gratefully acknowledge this support.

1. Other foreign-born groups also are highly concentrated. For example, 64.6 percent of the Cuban-origin population resided in Florida in 1990. However, these groups have absolute numbers that are low in comparison to the Mexican-origin population. The Cuban group, for example, numbered 1.0 million in 1990, or 7.7 percent of the Mexican group.

2. We are presently unable to estimate the model with more than nine inputs, but this is five more inputs than is found in the typical production-theory approach.

3. J = 9 in all models.

IMPACTS OF MIGRATION

Mexican Immigrants and Mexican American Political Assimilation

*Michael Rosenfeld**

There are many political dimensions of Mexican immigration and Mexican American life in the U.S. Political life in the U.S., as elsewhere, includes the realms of routine electoral politics where candidates seek votes, symbolic politics where images of immigrants may be put to a variety of uses, legislative politics where rights and privileges of different groups may be gained or lost, and so on. The political relationship between Mexican immigrants and Mexican Americans (a term which I will use in this paper to refer to U.S. born persons of Mexican descent) is a multidimensional one that has evolved over time as the Mexican American community has evolved politically, and as U.S. immigration law has changed.

While at first it may seem that immigrants have little direct effect on routine electoral politics in the U.S., because they cannot vote, there are in fact a number of links between immigrants and electoral politics. Immigrants effect electoral politics directly through census enumerations and decennial redistricting. U.S. congressional districts, and all state legislative districts are apportioned on the basis of *persons*, rather than on the basis of citizens or adult citizens because of the wording of article 1, section 2 of the U.S. constitution (the U.S. is quite unusual in
